The success of this application was remarkable: in many cases it had the effect of doubling the length of vision. In some persons I found the iris was not much dilated, but very torpid. In these cases I applied the concentrated tincture of pepper, made of the same strength and in the same manner as the tincture of ginger. This I used until I observed that the iris had obtained a greater power of contraction and dilatation; after which I had again recourse to the tincture of ginger. This plan of treatment has been attended with the most signal success, and persons who were extremely short-sighted have very soon become enabled to lay permanently aside their concave glasses. The best method, I may observe, of testing the improvement of the sight during this treatment is, not by taking a printed book, and holding it near, and then at a greater distance from the eyes: this range of vision is much too limited: it is better to fix the attention of the patient upon a distant object, such as the brass key-hole of a door, and by his stepping some paces backwards, so as to place himself at a greater distance from it, he will soon discover the progress he is making.

So important a discovery as this will, I hope, be fairly tested by the members of our profession, who may rely on the success of the treatment I have recommended, if it be only judiciously and carefully carried out.

It is possible that the advantage derived from the tincture as above described may be ascribed to the alkaloidal principle,

piperis, which is held in solution in the tincture of pepper.

I remain, sir,

Your obedient servant,

A. TURBULL, M.D.

16, Manchester Square,
November 9, 1850.

Medical Intelligence.

TESTIMONIAL TO MR. J. F. CLARKE, VICE-PRESIDENT OF THE MEDICAL SOCIETY OF LONDON.

ON Thursday the 7th inst., a very numerous and highly influential meeting of the members of the profession, was held at the house of Dr. Webster, Brook-street, Grosvenor-square, with the view of promoting a subscription for the purpose of presenting a testimonial to Mr. J. F. Clarke, for the services he has rendered to the Medical Society of London, and the profession generally.

Dr. Webster, in stating the objects of the meeting, paid a high compliment to the useful literary labours of Mr. Clarke, and observed, that the assiduity and ability evinced by that gentleman during a rather long career entitled him to the thanks of the profession generally.

The first resolution, proposed by Dr. Chowne, and seconded by Mr. Coulson, was to the following effect:—

That Mr. Clarke, having by his literary exertions during many years, and by the faithful discharge of various important duties, including his valuable reports, materially contributed to extend the fame and usefulness of the London Medical Society, has established for himself strong claims upon the good opinion of the profession generally.

2. It was moved by Dr. Moore, and seconded by Mr. J. B. Brown,

That a subscription be now entered upon to present Mr. Clarke with a suitable testimonial in accordance with the previous resolution.

3. It was moved by Dr. T. Smith, and seconded by Mr. Robert Wade,

That Dr. Clutterbuck and Mr. Coulson be requested to act as treasurers.

It was moved by Dr. Winslow, and seconded by Mr. W. Harvey,

That the following gentlemen be appointed a Committee, with power to add to their number:—Dr. Golding Bird, Dr. Chowne, Dr. Daniell, Professor Erichsen, Professor Fergusson, Mr. Hancock, Mr. Harvey, Mr. Bird, Dr. Moore, Dr. Webster, Dr. Winslow, Mr. Wade, Mr. Stratton, Dr. Sibson,—to carry out the object pro-

posed, and to report at a future meeting of the subscribers—five to be a quorum.

Mr. Wing, and Mr. Borlase Childs, have consented to act as Honorary Secretaries. About one hundred pounds were subscribed in the room.

PROHIBITION OF THE SALE OF WOORARA POISON IN FRANCE.

THE French journals lately drew the attention of Government has been drawn by M. Bernard to the danger arising from the sale of *Woorara* poison. An order has been issued to prohibit its sale by including *Woorara* in the list of poisons which are not allowed to be sold except under certain legal restrictions.

DEATH OF M. BURRAUD-BROFFET, M.D.

THE last number of *D'Union Médicale* announces the death of this gentleman, who was for many years well-known in London as a writer on medical subjects, and the conductor of an Anglo-French periodical. About a year since he emigrated to San Francisco, in California, taking the long sea journey by Cape Horn. He died soon after his arrival in California, from an illness contracted during the voyage.

Selections from Journals.

ADVANTAGES AND DISADVANTAGES OF ETHER AS AN ANÆSTHETIC.

THE *advantages* of sulphuric ether are, according to Dr Hayward, "its entire safety, the ease with which it is administered, and the slight inconvenience which follows its administration. I have already stated that I have never known its inhalation followed by a fatal or alarming effect, and there is reason to doubt whether death has in a single instance been produced by it, when it has been properly administered. One patient is said to have lost his life by its inhalation at the hospital in Auxerre, in France. This took place in August, 1847. The details of the case are not given, with such minuteness as to enable any one to form a satisfactory opinion. It occurred, however, not long after the discovery, before the best mode of exhibiting it was adopted; and the *post-mortem* appearances indicated, as far as any opinion could be formed from them, that death was caused by asphyxia. In a careful examination of some of the leading medical journals of Europe and this country, published during the last fifteen years, I have not been able to find another case in which life was destroyed by the inhalation of sulphuric ether, and there is reason to believe, as I have already inti-

mated, that death would not have taken place in this instance if the lungs had been abundantly supplied with atmospheric air. It is only wonderful that an agent of such power, used as it often has been in the most reckless manner, by unskilful and ignorant persons, should not have caused far more disastrous results than any that have hitherto been made known. It teaches us that though it should be used with caution and confided only to skilful hands, the dangers from its use are far less than our preconceived opinions had led us to believe.

"There are no ill consequences from its use. If it be breathed only for a short time its effects usually pass off in a few minutes. I have never known them to continue for more than an hour; and in this case the patient had been kept under its influence for forty-five minutes. Nausea and vomiting are not frequent, unless it is inhaled soon after food has been taken. I have not seen convulsions follow its exhibition, nor any delirium, except a slight and transitory kind, such as arises from intoxicating liquors. I confess that I was much surprised to learn, by carefully watching its effects, to what a small extent and for how short a time it disturbed the functions of the nervous system, and how rare it was to find headache among the consequences of its inhalation.

"The only objections of which I am aware to sulphuric ether as an anæsthetic agent, are its pungent odour, which is offensive to some persons, and the no inconsiderable degree of irritation which its inhalation occasionally produces in the air passages. This irritation, I am confident, may be in great measure prevented by proper attention to the mode of its exhibition and the quality of the article used. Admitting these objections to be as great as they have been said to be by those who have urged them with the most earnestness, they do not in my opinion counterbalance the advantages, and I have no hesitation in saying that I should give it the preference over any other article with which I am acquainted, that is used for the purpose of producing insensibility."—*American Journal of the Medical Sciences*, July 1850.

POISONING WITH WINE THAT HAD CONTAINED LEAD-SHOT.

THE following is an additional example of the danger of cleaning wine-bottles with lead-shot:—

Eight of the pupils of the Jesuit School at Dole having partaken, with their Superior, of a bottle of wine, were suddenly seized with symptoms of severe colic, and in three hours (?) the Superior died. It was found that the bottle had contained several shot, which had been acted upon

by the acid of the wine.—*Journal de Chimie Médicale*, Octobre 1850.

X

TREATMENT OF CHOREA BY FRICTIONS WITH CHLOROFORM.

M. GASKEZ has published three cases of chorea cured by the topical application of chloroform.

The first was that of a child, seven years of age, in whom the disease was caused by fright. A liniment composed of equal parts of chloroform and oil of sweet almonds was rubbed, night and morning, along the course of the spine. From its first employment the violence of the muscular movements was moderated, and in six days the patient was cured.

The second case was that of a boy, twelve years of age, in whom the disease had appeared two months before as the effect of fright. The spasmodic movements were so violent that he could hold nothing in his hands, nor walk without help. At the end of a fortnight, under chloroform frictions, the disease had disappeared. A relapse, however, occurred, which was cured in two days by a return to the same means.

In a third case, of five months' standing, the result, also, of fright, the symptoms disappeared in seven days under chloroform frictions.—*L'Union Médicale*, Oct. 31, 1850.

COURSE OF LECTURES

ON

DISEASES OF THE HEART.

Delivered at St. Vincent's Hospital during the Session 1849-50.

By O'BRYEN BELLINGHAM, M.D.

Fellow of, and Member of the Court of Examiners of, the Royal College of Surgeons in Ireland, and one of the Medical Officers of the Hospital.

LECTURE XIV.

GENERAL SIGNS OF HEART DISEASE.

Indirect or secondary symptoms—Congestion—Causes of—Mode of production of—Organs in which congestion most readily occurs—Effects of congestion upon different organs—Congestion of the lungs—Edema of the pulmonary tissue.

Indirect or Secondary Symptoms of Cardiac Disease.

Congestion.—The secondary, the indirect, or the remote symptoms of cardiac disease, are, in the majority of cases, the result of some impediment to the return of the blood conveyed by the pulmonary veins to the left side of the heart, or to that of the venous blood from the system generally, through the right side of the organ, which in their turn are frequently the result of an obstruction to the free passage of the blood through the chambers of the heart. The blood, being retarded and delayed in the large veins, accumulates in the smaller vessels and capillaries; they become distended, dilated, and tortuous; their healthy state of elasticity or tone is impaired or diminished, and congestion is the result, which may be limited to the lungs and bronchial mucous membrane, or may extend to the liver, spleen, kidneys, and gastro-intestinal mucous membrane, or to the brain, causing more or less derangement of the function of these organs.

When we speak of congestion, therefore, we mean a state in which there is a preternatural accumulation of blood in the minute veins and capillaries, with a weakened, retarded circulation, and a loss or deficiency of tone in the coats of the dilated vessels; in consequence of which they "react imperfectly upon the blood transmitted to them," and are unable to "transmit the force of the current in the propulsion," "vessels which have lost th becoming inelastic and tortuous,

the very stagnancy of the blood in them, opposing an increasing obstacle to its passage through them."

The cause of the motion of the blood in the capillaries is now generally considered to lie in the impulse given to this fluid by the contraction of the ventricles. An experiment which was performed by Dr. Sharpey seems to confirm this. "A syringe, with a hæmadynamometer, to show the amount of pressure used, was adapted to the aorta of a recently dead animal, the vena cava being divided; warm water was then injected, and, with a force which raised the mercury in the hæmadynamometer only three inches, the water passed through the capillaries, and out of the vena cava. When the pressure was increased so as to raise the mercury six inches, the flow was very free; and on adapting another hæmadynamometer to the vein, the pressure in this was found to rise as high as three inches. The pressure thus used in the arteries (six inches of mercury) was not greater than the natural pressure in the arteries of a living animal; and the pressure transmitted to the veins (three inches of mercury) was greater than that in the veins of a living animal,—thus showing that the force of the heart sustained by arterial tension is quite adequate to effect the circulation without other aid."

Hence, when the contractile power of the left ventricle is weakened, owing to dilatation of its cavity, to attenuation of its parietes, or to softening of its tissue, the blood must necessarily pass with greater difficulty through the capillaries, and congestion will be liable to ensue; while, if the circulation through the left side of the heart is impeded, the capillaries of the lungs will become congested in the first instance, followed by general venous congestion and the train of symptoms presently to be described.

It was at one time a very general opinion that cerebral congestion, or apoplexy on the one hand, and hæmoptysis or pulmonary apoplexy on the other, had their cause, the former in hypertrophy of the left ventricle, the latter in hypertrophy of the right; their occurrence was, in fact, looked upon simply as an example of cause and effect, the increased force with which the thickened ventricle transmitted the blood to the brain or lungs being considered sufficient to produce all the signs of congestion of these organs, terminating in serous or sanguineous effusion, or in rupture of the coats of the small vessels.

This theory of the cause of congestion is supported by pathological as the lungs are concerned, be exploded, the congestion in the

result of cardiac disease being much more frequently the result of obstruction to the free passage of the blood through the chambers of the left side of the heart. Because, even though the propulsive power of the ventricles is increased, if there is no impediment to the return of the blood by the veins, the circulation will only be carried on more vigorously, the veins returning the blood as rapidly as it is transmitted to the arteries. Indeed, congestion is much more liable to occur when the force with which the blood is propelled by the ventricles is diminished, as in dilatation and attenuation of the ventricles, or in softening of the tissue of the heart, than when this fluid is propelled with increased force by an hypertrophied ventricle.

Congestion may likewise be the result of long-continued determination of blood to a part, and hence is not unfrequently the effect of a previous attack of inflammation, which, when it has lasted long, or been repeated, leaves behind a state of over-distension of the vessels, and of weakness of their coats, which renders the patient liable to a fresh attack of inflammation in the same part. This appears to be the reason, that a person who has previously been the subject of bronchitis, tonsillitis, or conjunctivitis, is more liable to a return of inflammation in the same part than in any other, after exposure to cold or any other cause capable of giving rise to it.

Over-distension of the minute vessels appears to be not only an effect of congestion, but a cause of the continuance of this state. "The blood-vessels, in their healthy condition," Dr. Williams* observes, "are so constituted as to make the most of the heart's propulsive power, and transfer it through their whole length; but when dilated, tortuous, flaccid, and otherwise altered, they misdirect and exhaust it; it is partly expended in distending and dilating the nearer portion; whilst a sufficiency does not remain for the onward propulsion of the blood, which, therefore, stagnates and accumulates in the congested blood-vessels." "When the circulation is feeble, and the tone of the vessels weak, these causes of congestion operate," he adds, "more readily and more permanently than when the circulation is vigorous; yet these congestive affections, the result of weakness, are often mistaken for inflammation. Many of the pains and ailments of delicate females are of this nature; and, although temporarily relieved by depletory measures, are to be permanently counteracted only by tonic means, which promote the vigour and equality of the circulation."

When congestion is carried to an ex-

treme degree, or has lasted for a considerable time, the overloaded and overdistended vessels relieve themselves by allowing the more watery parts of the blood to transude, and serous effusion occurs, or the blood itself may escape, or rupture of a vessel and extravasation of blood may occur.

Long-continued congestion frequently leads to more or less alteration of the tissue of the congested organ or part; its size is frequently increased; and this may or may not be accompanied by pain, or by tenderness on pressure. This is more frequently witnessed in the liver and spleen than in other organs; and, if the cause continues long in operation, the increase in size may be permanent. Dr. Clendinning* has shown that the lungs acquire increased development and weight under such circumstances. The functions of the organ the seat of the congestion almost always likewise suffer; and, in secreting organs, the congestion may occasion either diminution, suspension, alteration, or increase of the secretion.

In the great majority of the cases which we are considering congestion may be traced to one or other of the following causes—viz., 1st. To feebleness of the heart's action, the result of dilatation of the left ventricle, of attenuation of its parietes, or of softening of its muscular tissue, or to two of them combined; in consequence of which the contractile power of the left ventricle is diminished, and its systole is insufficient to propel the blood through the systemic capillaries; 2ndly. To free regurgitation through the tricuspid orifice, the result of dilatation of this opening, combined with hypertrophy and dilatation of the right ventricle; by which the return of the blood from the venæ cavae to the right auricle is greatly impeded, leading to its accumulation, first in the large venous trunks, and next in the smaller veins and capillaries; and 3dly. To a contracted state of the mitral orifice, impeding the passage of the blood from the left auricle into the left ventricle, or to a state of the mitral valve or orifice which permits free regurgitation through it; owing to which much of the contents of the left ventricle is transmitted backwards into the left auricle at each systole. In the first of these cases the congestion commences in the capillaries of the systemic circulation, and extends to the veins; in the second it commences in the large veins, and extends to the capillaries; in the third it commences in the pulmonary capillaries, and extends to the large veins.

For instance, when the left auriculo-ventricular orifice is much contracted,

* Principles of Medicine.

* Croonian Lectures: MED. GAL.

there will be a permanent impediment to the passage of the blood from the left auricle into the left ventricle; and, as all the blood in the system must pass through this orifice, if it is much diminished in size, the left auricle will become distended, and the return of the blood by the pulmonary veins will be impeded; congestion of the pulmonary tissue, and of the bronchial mucous membrane will follow, which will react upon the right auricle and ventricle; the latter will become dilated, and the former hypertrophied. The entrance of the blood conveyed by the *vena cava* to the right auricle being impeded, these vessels become distended. The hepatic veins and the portal circulation suffer next; congestion of the liver, spleen, kidneys, and gastro-intestinal mucous membrane follows, and, the free return of the blood by the jugular veins being impeded, congestion of the head, face, or of the brain, may ensue.

When the left auriculo-ventricular orifice is dilated, or when the mitral valve is diseased, and incapable of closing the orifice, and free regurgitation into the left auricle occurs at each systole of the ventricle, the same results will follow, but in a somewhat less marked degree than when extreme contraction of the orifice exists. According to Dr. Blakiston,* however, this is the most frequent cause of pulmonary congestion. "Of all the forms of valvular disease, incompleteness of the mitral valves was found," he observes, "to be the most constant and direct cause of pulmonary congestion." "Mitral regurgitation existed in almost every one of the cases where pulmonary congestion formed the leading symptom."

When the parietes of the left ventricle are thinned, and its cavity is dilated, or when the muscular tissue of the ventricle is softened, the weakened organ is unable to propel the blood with sufficient force to pass through the capillaries of the systemic circulation, and they become congested. Eventually, the left ventricle, owing to its inability to empty itself, becomes distended, followed by distension of the left auricle. The pulmonary veins have then a difficulty in returning their blood; and the same train of symptoms may follow as where the valves or orifices of the left side of the heart are diseased, and impede the circulation through it.

When the right auriculo-ventricular orifice is dilated, and much of the contents of the ventricle regurgitates into the auricle at each systole, particularly when the right ventricle is at the same time hypertrophied, the return of the blood by the *vena cava*

to the right auricle will be impeded, which will react upon the venous system throughout the body, and will be followed by congestion of the liver, spleen, and gastro-intestinal mucous membrane, as in the cases where the congestion commences in the pulmonary capillaries. According to Dr. Blakiston, this is the most active cause of general venous congestion. "When regurgitation at this orifice takes place to any extent, it is impossible to conceive," he says, "a more powerful obstruction than is thus offered to the passage of the blood from the veins into the heart by a strong counter-current forced backwards by the systole of the right auricle." Dr. Blakiston seems likewise to be of opinion that regurgitation through the tricuspid orifice, as a cause of congestion, had been overlooked until he called attention to it. In this I cannot agree with him: indeed, so far as I have had the opportunity of observing, dilatation of the tricuspid orifice, with hypertrophy and dilatation of the right ventricle, scarcely ever occurs, except as secondary to valvular disease, at the left side of the heart.

The organs in which congestion the result of cardiac disease most readily occurs are, as a general rule, those which are most vascular—viz., the lungs and bronchial mucous membrane, the liver, spleen, kidneys, and gastro-intestinal mucous membrane, and the brain. Indeed, the secondary or indirect symptoms of cardiac disease depend essentially upon the amount and degree of congestion which it occasions, and they vary according to the organs particularly engaged.

In the slighter forms of congestion, the functions of the organ the seat of the congestion may be little affected: in the advanced stage its functions are frequently seriously impaired. Thus in congestion of the lungs and bronchial mucous membrane we have dyspnoea, passing into orthopnoea, with oppression, cough, and expectoration, which may or may not be followed by hæmoptysis or pulmonary apoplexy; the secretion from the bronchial mucous membrane is often remarkably increased, and this may prove one of the most troublesome symptoms. Congestion of the liver is accompanied by an increase in size of the organ, and by impeded or vitiated secretion, or by arrest of the biliary secretion, frequently with pain or tenderness on pressure. When the gastric mucous membrane is congested the disturbance of function may be indicated by increased or altered secretion, or we may have nausea, or antiperistaltic action of the organ, or pain may be the most prominent symptom, or loss of appetite may be alone complained of. When the spleen is congested the organ sometimes attains a remarkable size:

* Practical Observations on Diseases of the Chest.

this, however, is more frequently observed as an effect of acute than of cardiac disease. When the liver and gastro-intestinal mucous membrane are both congested, we may have pain, deranged digestion, loss of appetite, flatulent distension, vomiting, hepatic derangement, hæmatemesis, diarrhoea, hæmorrhoids, jaundice, or ascites. When the brain is congested its sensibility is sometimes impaired, sometimes increased, and we may have headache, tinnitus aurium, vertigo, sense of weight in the head, confused vision, or disordered volition, or a semi-comatose state, which, in extreme cases, may terminate fatally, with or without the rupture of any vessel. Finally, when the kidneys, and the venous system generally, are congested, we have œdema, slight at first, and commencing in the most dependent parts, but eventually becoming general.

Congestion of the Lungs.

The lungs, from their physiological position between the right and left chambers of the heart, must suffer whenever the circulation through the heart is not free, or when disease to any extent exists in the valves or orifices of the left side of the organ. Thus, when the mitral valve is diseased, and the orifice is contracted, the left auricle, being unable to empty itself, becomes distended, and the blood returning by the pulmonary veins cannot freely enter the auricle; the right ventricle at the same time continuing to transmit the blood by the pulmonary artery, the capillaries of the lungs become overloaded, and the pulmonary tissue and the bronchial mucous membrane congested.

When the mitral valve imperfectly fulfils its functions, and much of the contents of the ventricle is transmitted backwards into the left auricle at each systole of the left ventricle, the left auricle will remain distended, the pulmonary veins cannot empty themselves, and the same results follow as where the mitral orifice is contracted.

When the aortic valves permit free regurgitation into the left ventricle, this reacts upon the left auricle, and the effects are propagated backwards to the lungs, but in a much less injurious degree than when the mitral orifice is much contracted. When the aortic orifice is diseased, so as to obstruct the orifice considerably, the same results sometimes follow as where considerable contraction of the mitral orifice exists. "It appears (Dr. Blakiston observes) that a considerable amount of disease of the aortic orifice may exist for a number of years without seriously affecting the general health, more particularly if hypertrophy of the left ventricle is joined with it; and that, consequently, this affection has little or no direct influence in re-

tarding the venous circulation, and producing engorgement of the vessels of the pulmonary or general circulation."

The congestion of the lungs and bronchial mucous membrane which occurs under such circumstances is always of the passive form, and is always a secondary or consecutive lesion. When it has lasted long, or when the patient has suffered frequent attacks of it, a condition of the part remains in which inflammation, or a state approaching to it, is very liable to be set up, and sometimes by causes which would be incapable of giving rise to it in a healthy condition of the parts: hence we not unfrequently observe in addition a real determination of blood to the lungs, the result of inflammation of the parenchyma of these organs.

The important function which the lungs perform in the conversion of venous into arterial blood must obviously be seriously interfered with when the circulation through the pulmonary capillaries is retarded and impeded, and the minute vessels are considerably engorged. The capillary vessels of the lungs form, we know, a net-work around each vesicle or air-cell: they are exceedingly numerous, and in greater abundance in a given space here than in almost any other part of the body. Now as the blood must all pass through them before it arrives at the commencement of the systemic circulation, it is obvious that any impediment to its passage will be felt throughout the system; while, if the blood is prevented from undergoing the change from venous to arterial in the pulmonary capillaries, the pulmonary veins will convey venous as well as arterial blood to the left auricle. Hence, when the congestion is considerable in degree, and engages much of the pulmonary tissue, and the air-cells of the part scarcely permit of the entrance of atmospheric air during inspiration, the blood will be imperfectly oxygenated, its carbonic acid will be incompletely removed, and the renewal of the fibrine will be imperfectly accomplished; a mixture of venous and arterial blood will then circulate in the arteries, which is unfit for maintaining the functions of the various organs in a healthy condition, or for supplying nutriment to their tissue; the brain, the nervous system, the heart, and the other organs, the maintenance of the function of which depends upon a due supply of arterial blood, suffer; the muscular system receives less fibrine, the animal heat diminishes, and the entire system feels the depressing influence.

When the pulmonary capillaries have been congested for a long time, or to a considerable degree, the overloaded vessels are relieved by the transudation of the watery, saline, albuminous, and sometimes

of the fibrous portions of the blood; or the blood itself may be effused upon the surface of the bronchial mucous membrane, or into the air cells, or rupture of a minute vessel may take place, with extravasation of blood upon the mucous surface, or into the pulmonary tissue; accompanied by œdema of the pulmonary tissue, dyspnoea, which in extreme cases amounts to orthopnoea, cough, and watery expectoration; or hæmoptysis, and sometimes pulmonary apoplexy.

Long-continued congestion not only interferes with the functions of the congested organ, but it also frequently affects its nutrition and structure. "It generally tends," as Dr. Williams observes, "to cause an increased deposit in them, constituting a variety of hypertrophy." "In the lungs, long-continued congestion may," he remarks, "cause hypertrophy of the inter-vesicular and interlobular textures, and in some cases partial consolidation of the vesicular structure itself." "Such changes," he adds, "are frequently met with in connexion with long-standing disease of the heart, and abound most in the posterior parts of the lungs, and near their roots, the most vascular parts."

Œdema of the Lungs.

When the congested capillaries of the lungs have relieved themselves by allowing the serous or thinnest portion of the blood to transude, and when the air-cells, the minute ramifications of the bronchial tubes, and the interlobular cellular tissue, have become infiltrated with this fluid, it constitutes the state known under the name of œdema of the lungs; and, as in œdema of the extremities, the fluid gravitates to the most depending parts, and will be found to occupy the base of the lungs.

Œdema of the pulmonary tissue is necessarily, therefore, a symptom only of the advanced stages of cardiac disease, and the forms of disease with which it is usually associated are those in which a considerable impediment exists to the free passage of the blood through the left chambers of the heart, particularly valvular disease. It is more common in the obstructive lesion of the mitral orifice than in any other; indeed, few cases of this form of disease go through their stages, without this condition being present in a greater or less degree, and it is usually preceded by general anasarca of the cellular tissue.

Œdema of the lungs, although no unfrequent effect of cardiac disease, is by no means limited to diseased states of the heart, but is met with in several other morbid conditions; thus it may accompany general dropsy; it is observed in chronic bronchitis, and pertussis; it follows the resolution of

pneumonia, and it is met with as a sequel of measles and scarlatina.

This condition of the pulmonary tissue is always accompanied by more or less dyspnoea, by cough and expectoration, frequently of a thin mucous or serous fluid, as well as by certain physical signs,—the most remarkable of which are dullness on percussion, and a moist subcrepitant rûle on auscultation of the base of the lungs,—but upon which it is not necessary to delay here.

[To be continued.]

THE PERIOD AT WHICH IODINE APPEARS IN THE URINE.

DR. DALTON states that he observed the appearance of iodine in the urine in seven cases, and in many of them it was detected at the same time in the saliva. In order to determine the time which is necessary for iodine to appear in the urine, the following experiments were instituted. On the 21st of February, at five P.M., I took half a drachm of the syrup of the iodide of iron, and examined the urine afterwards, at intervals of ten minutes. The portions passed at ten and twenty minutes past five showed no indication of iodine; but at half-past five a strong purple colour was produced by the addition of starch and nitric acid. This reaction continued throughout the evening, and urine passed at seven the next morning struck a deep indigo with the same reagents. At nine A.M. the colour was less marked; and from this time it continued to grow fainter and fainter, till forty minutes past four P.M., nearly twenty-four hours from the time of taking the medicine, after which no further reaction was perceptible.

The next observation was made with regard to the accumulation of iodine in the system, and the time necessary for eliminating a large quantity. Two patients in the Massachusetts General Hospital had been taking iodide of potassium, one for six, the other for eight weeks. During the greater part of this time, they both took the medicine to the amount of one drachm per day. On the 24th of February, the medicine was omitted for each. The urine of both patients at this time gave a nearly black colour with starch and nitric acid. It was then examined every twelve hours, soon after being passed. In seventy-two hours the colour produced was very faint, so that in one case it was doubtful whether it existed or not; and in the other it was distinct on first dropping in the nitric acid, but disappeared by agitation. In twelve hours more, all trace of iodine had disappeared from both specimens.—*American Journal of Medical Sciences.*

ON THE
TREATMENT OF OBSTRUCTION OF
THE BOWELS.BY EDWARD WELLS, M.D., OXON.,
F.R.C.P.*(Read before the Reading Pathological
Society.)*

In venturing to make the following brief remarks upon the treatment of obstruction of the bowels, I do so principally with a view of causing a discussion upon this subject, and of not only recording my own experience, but also of eliciting that of others.

It cannot, I think, be denied, that of late years the treatment of diseases in general has taken a right direction, and made a rapid improvement. Both in the domain of medicine and of surgery the preservation of life and limb has largely ensued from the adoption of a conservative policy. Putting aside the increased amount of good we are enabled to effect at the present day, it is no small proof of our progress in therapeutics that we do much less injury to our patients than was done by our predecessors.

This improvement in practice is perhaps evidenced in no disease more strongly than in that of obstruction of the bowels. Instead of the old custom of reiterating cathartics upon cathartics, of hunting the Pharmacopœia for purgatives still stronger than those already administered, of pouring in quicksilver as if the intestinal tube had a continuous descent, the practitioner of the present day wisely attempts to soothe rather than to excite the already irritated intestine. He knows that the mere inaction of the bowels is of itself of very secondary importance, that there are cases, in which individuals pass weeks and weeks without having a motion, and feel none the worse, and he is rather anxious to remedy the cause, knowing that when this is removed the effect will follow.

In considering on the present occasion the treatment of obstruction, I do not intend to refer to those cases which arise on the one hand from causes acting

externally to the intestinal tube, such as tumors, either malignant or otherwise, which by pressure mechanically occlude the channel, or, on the other, to those which arise from causes acting *internally* to the intestinal tube, such as hardened feces or calculi, such as originate from the use of magnesia. Neither do I refer to those cases which depend upon the strangulation of a hernia. These cases each require their peculiar mode of treatment, and the last-mentioned belongs to the province of surgery.

The cases which I have in view at present are those in which there is no demonstrable cause of the obstruction, and in which the point of obstruction is situated somewhere in the small intestines.

I will now suppose an instance of such a case:—

You are called to a patient, who informs you that he has had no proper relief from the bowels for the last seven or eight days, that he has been to the druggist, and taken black dose upon black dose, pill upon pill, and that they are all in him, and he wants to know what he is to do next. He tells you further that it is true he has been to stool once or twice, or perhaps even oftener during the time, that he has perhaps on each occasion passed something, but he is sure it is not what he ought to have passed. In short, to use his own expression, although he has occasionally had a scanty evacuation, he is convinced that "*nothing has gone through him.*" Upon examining the abdomen, you find some distension around the umbilicus, with a degree of tenderness on pressure. This last symptom varies from that slight shade in which the patient can hardly say whether the pressure relieves his pain or not, up to decided tenderness on the least touch. In mild cases the patient will tell you he feels very well, excepting the obstruction, but the knowledge of its existence makes him very uncomfortable. In other cases there is some degree of sickness conjoined, merely perhaps occasioned by the purgative draughts. In severer cases the sickness is more permanent, mucus or bile being rejected from the stomach. In such instances we should expect the tenderness on pressure over the bowels to be greater, though still not in any degree approaching to what usually

occurs in peritonitis. There will also be a rumbling of flatus in the intestines, and the patient will say he feels the wind pass downwards to a certain point and then stop. All this time the pulse is not perhaps accelerated, it is generally weak; the tongue is moist and often clean; the urine, provided the obstruction be not situated high up in the bowels, is not necessarily affected, though generally high coloured.

Under these circumstances, and especially in the milder cases, the first thing perhaps that you do is to order a large enema to be thrown up. It is found to traverse the large intestine easily; the patient assures you that he feels it go as far as the ilio-cæcal valve, and after a short time it returns without any tinge of fecal matter. The obstruction is not in any part of the colon, but somewhere in the small intestine.

What treatment should, then, be adopted? In the severer cases, where there is pain upon pressure, distension of a portion of the intestine, a rumbling of flatus, and frequent vomiting, it will be said that the line of treatment is easily chalked out; that, whatever the cause of the obstruction, we have inflammation superadded; and that our treatment must be directed to subdue the latter. This is quite true; and in such well-marked cases I do not think there would be much chance of the case being misunderstood. But we must remember that these severe instances of the disease are only the consequence of a continuation and aggravation of the symptoms of its milder forms. We must not forget that the most simple case of obstruction is liable to run on into a fatal form, if, with the view of obtaining an action of the bowels, we are incautious in the prolonged use of irritating medicines. Finding that the patient's chief discomfort arises from the fact of the bowels not acting, that he professes himself as feeling otherwise well, we are, perhaps, rather too liable to fall in with his own fancies, and just give him one more dose.

Now, in these cases what ought we to do? In the first place, abstain entirely from all purgative medicines. It will be much better to err in not giving sufficient aperients, than to err in giving too much. The first thing to do is to compose the patient's mind by informing him that there is no hurry

for the bowels to act; that if he waits patiently, they will be sure to act in time; to tell him instances of persons who have gone a long time without any action of the bowels, and have done well.

Next, in these cases of obstinate obstruction I have great faith in the lancet, where it can with safety be used. It has seemed that a slight degree of faintness produced by blood-letting has acted very beneficially in removing the exciting causes of the obstruction, probably by the general relaxation which the faintness itself occasions. By putting the patient in an upright position, and bleeding him until he begins to feel slightly faint, I think we are quite safe not to do him any harm. If he is of a weak, nervous temperament, a very few ounces will produce the desired effect. If he be strong, he will afford to lose more. Where, however, the debility of the patient forbids the use of the lancet, it will be as well to apply leeches around the umbilicus. These act, probably, by relieving the local congestion, which is either the cause or the effect of the obstruction.

These measures premised, the safest plan is, I think, to put the patient upon repeated doses of calomel and opium. Even if inflammation be totally absent, the exhibition of these two drugs is likely to be attended with the best effects. The opium soothes the bowels already irritated by the repeated cathartics: it allays the over-excited peristaltic action; it relaxes any contingent spasm, and quiets the patient's mind. To effect these objects, it must be administered in sufficient doses—such as gr. ʒ to gr. j. every four hours. The calomel, by improving the secretions, and exciting the action of the liver, tends to remove the cause of the obstruction. And if this happen to depend upon a partial enteritis, the combined action of these two medicines would hold out the best hopes of a successful treatment. If the calomel be sufficiently guarded by opium, there is not, I think, any fear of its producing any serious irritation of the bowels.

While using these remedies I should be in no hurry to accelerate the action of the bowels by aperients. I should rather wait until they begin to act of themselves, as they generally will; and then, provided no inflammatory symp-

toes were present, there would be no objection to administer a dose of castor-oil to aid their propulsive efforts. In these cases it is also better to delay the administration of aperient enemata until the bowels are acting of themselves. Previously to this they appear to add rather to the patient's discomfort, probably by the distension they occasion in the large intestine, which reacts upon the parts already distended by the obstruction.

When there is no tendency to sickness it is better to allow the patient to take food, in the shape of gruel, by the mouth. It prevents that sense of sinking which he often experiences, and it probably acts in some degree mechanically in propelling the contents of the intestinal tube.

In those severer cases, where there is frequent sickness, with pain in the bowels, and a rumbling of flatus, the above measures will be still further indicated. But there will also be other things which it will then be necessary to attend to. In these cases it is of great importance to abstain from giving any food by the mouth for some days. A tea-spoonful of cold water should be put into the mouth from time to time to allay the patient's thirst. His support should be entirely entrusted to beef-tea injections. It is proved that these are sufficient to maintain the strength for some time—at any rate, for a period sufficient to allay the irritating symptoms, which forbid the exhibition of food by the mouth. This part of the treatment I am inclined to consider as of the highest importance; for as long as food is continued to be administered by the mouth, and is rejected by vomiting, there will be little chance of arresting the inversion of the peristaltic action of the intestinal tube. The nutritive enemata should be of small bulk, not exceeding at the outside a quarter of a pint; otherwise they will not only not be retained, but they will add to the patient's sufferings. They should be administered at regular intervals of four hours. When there is much rumbling of the intestines, or when there is a difficulty as to the retention of the injections, it is advisable to add to them a certain proportion of laudanum.

I have confined my remarks on this occasion to the treatment of these cases

of obstruction: I have said nothing of their *pathology*. I shall probably be told that the severer cases which I have described are nothing but cases of enteritis; and this is probably true to a certain extent. But what I have been most anxious to discuss is the treatment of the milder cases. Whether they also are not most frequently cases of partial and slight enteritis I will not take upon myself to say, but I feel convinced that the safest way of treating them is to suppose that they are such, and to treat them accordingly. It may be said that some of these cases arise from intussusception or internal hernie. There is no doubt that this is sometimes the case, though, I suspect, less frequently than is generally supposed; but, if it were so, the treatment I have recommended would answer better than any other to this state of things also.

ON THE COINCIDENCE OF ECLAMPSIA AND ALBUMINURIA.

M. HIPPOLYTE BLOT submits the following conclusions on this subject:—

1. Albuminuria is frequent in pregnant women.
2. In almost all cases it is the result of a simple functional hyperæmia of the kidney.
3. It is remarkable and inexplicable, that *primiparity* seems to be a predisposing cause.
4. Besides the presence of albumen in the urine, other signs of this condition may be observed,—such as œdema and lumbar pains.
5. The albuminuria of pregnancy is almost always free from febrile excitement.
6. In nearly every instance the albuminuria disappears a few hours after labour.
7. This condition of pregnancy is free from danger when uncomplicated with cerebral congestion; it has no influence on the course or termination of gestation, on the development of the fœtus, on the duration of the labour, nor on the subsequent natural puerperal state.
8. Every case of eclampsia seen by M. Blot has been accompanied with albuminuria.
9. The relation between the two is obscure; they may depend upon sanguineous congestion occurring at the same time in the kidneys and cerebro-spinal centre.—*L'Union Médicale*, Oct. 10, 1850. x

ON
CARDIAC AND AORTIC DISEASES.

By R. H. A. HUNTER, Esq.,
Staff Surgeon.

HAVING already written so much of these diseases in India (to wit, between 1834 and 1843, in the "India Journal of Medical Science," and "Transactions of the Bombay Medical and Physical Society"), it will be impossible altogether to avoid repetition, and particularly as since that period we have added little to our store of observations; not, however, because we have not met with cases since, both in the East and West Indies, and also in England, but because we have had less favourable opportunities for watching their progress, and proving afterwards or otherwise the diagnosis by post-mortem examinations. Nor would we have ventured, perhaps, to resume the subject, had we not, when in the West Indies only two years ago, noticed a paper in the "MEDICAL GAZETTE" setting forth the rarity of such diseases in the East; for though the error was subsequently corrected by Dr. Morehead, formerly secretary to the Bombay Society, it may not be so generally known that they are there even more frequent and fatal, at least among the European soldiery, than in England; and here we may have the less hesitation, as it is to our own former writings Dr. Morehead has directly appealed. In our remarks we propose the following order:—First, to consider the character of these diseases as they occur in the East Indies; second, the diagnosis; third, the causes; and fourth, the prognosis and treatment.

First, of the character:—In the East Indies there are at least three varieties of cardiac disease ordinarily met with—the pericarditic, the simple hypertrophy, and dilatation—and that which is the immediate subject of these remarks, the cardiac and aortic. Of the first we met with three cases in the 2nd or Queen's The subjects of all of them were delicate growing lads, from fourteen to eighteen years of age, sons of soldiers of the regiment, and for the most part brought up in India. Two were published in the Bombay Transactions, No. 2; but the third was first seen only a few months before we left. The second variety is

much more numerous: it is met with among recruits of the first and second years, and, like that mentioned by Dr. Hope as being common among the young servant-girls from the country in London, seems to depend upon an excess of nervous excitability, coupled with some undue proportion of the organ. In these, the climate, together with the duties of the soldier in India, so increase the inordinate action, and particularly if treated for that or other diseases by depletion (fevers especially, in malarious districts), that they are now very generally invalidated. The third, however, is the chief variety, and also the cause of the mortality under this head among the European soldiery. It is usually met with from twenty-eight to thirty years of age upwards; but by far the greater number with us have been from thirty to thirty-five. In all of this variety there is a marked similarity in the post-mortem appearances, differing principally in degree, but in some measure also in site,—that is, in some of the cases the valves are found more especially affected with chronic thickening, induration, and occasionally perforation; in others, the base of the aorta with dilatation, irregularity, and induration, occasionally with aneurism of the secondary or sacculated class; and all more or less associated with hypertrophy and dilatation of the left ventricle at least. Sacculated aneurisms are common also without cardiac complication about the arch, and again where the aorta enters the abdomen; but not a single case we remember in any of the secondary classes of arteries, the innominate excepted, and only one of the popliteal. This last occurred in Afghanistan, in a man forty years of age, as he supposed, from leaping over the water cuts, or other obstructions (there being no such thing as roads, even of the rudest description, in that country), and was operated upon afterwards with success at Kurachee, by taking up the femoral.

Second, of the diagnosis:—This, also, we fancied we had pretty well exhausted in India (Bombay Transactions, Nos. 1 and 5), that is, as far as our own personal observations extend; but since we returned to England, and have become better acquainted with the writings of others, we find the morbid murmur, indicative of mitral disease, which we have everywhere associated with the

second or diastolic sound, is here universally referred to the first, as is also the prolonged sawing at the base. We certainly claim priority in directing attention to the true site of the mitral murmur (Case of Madden in "The India Journal," 1835, and "Bombay Transactions" of 1836-7); but it may not at all times be so easy to determine to which of the true sounds it does actually belong, even with the aid of the finger on the pulse;—a corrective we have never omitted. But if ordinarily a regurgitant murmur, why should it not be more audible at the base in the direction of the current, where Dr. Hope (now evidently upon theoretical grounds) originally assigned it, rather than at the apex? And as to the prolonged sawing or rasping at the base, we have long been impressed with the belief that it is due rather to a churning in that situation from the reflux caused by the resiliency of the arteries. At all events, any palpable imperfection of the semilunar valves is by no means necessary. In morbid states of the base of the aorta, accompanied with hypertrophy and dilatation of the left ventricle, whether with or without valvular disease, we have always found this sound double,—to wit, a shorter, synchronous with the abrupt bellows, over the clavicle, and a longer, occupying not only the period of the diastole, but also of the normal interval. These are points, however, which will come better to be discussed afterwards.

In forming the diagnosis, we have hitherto pursued the following system:—that is, first to write down carefully the history as given by the patient himself, so as to avoid his statements being influenced by any crude opinions or suggestions of our own, then the results by "inspection," "palpation," and "percussion;" and not till all these have been carefully noted do we have recourse to the stethoscope. The abnormal murmurs, including all the varieties of "blowing," "sawing," and "rasping," we divide into two classes—the quick, or abrupt, and the prolonged, always of a sawing character. The first, according to the site, we associate with mitral or aortic disease, including aneurism; the other, with dilatation or other morbid states of the base of the aorta, or of the semilunar valves. If the first be more audible, or, as it usually is, confined to the region of the apex, it is in-

dicative of mitral disease; if at the base, upper part of the sternum, or in the course of the arteries (if indicative of disease at all, determining this by the character of the sound, &c.), it is aortic or aneurismal. In dilatation and other morbid states of the base of the aorta, as already mentioned, these sounds are double; the first, which is brief or abrupt, becoming bellows over the clavicles; the other, prolonged, is sometimes extremely loud, and, as it were, superficial over all the sternum. In sacculated aneurisms, also near the base, we have noticed the first sound somewhat prolonged, and of a hissing character; more squirting, loud, or forcible, however, than the diastolic murmurs. In exploring for deep aneurisms, whether for the sound or the impulse, we prefer without the stopper. Those most difficult to detect have been about the "innominata," or in the abdomen,—parts, in fact, not naturally sonorous. Two at the root of the neck, and several in the abdomen, have eluded our search altogether, even when directed to the very place by the symptoms. One of these, lodged between the upper portion of the sternum and the trachea, from the loud (steam-engine like) respiration, was mistaken for "tracheitis;" the other, at the root of the neck, from the persistent aphonia, for chronic disease of the larynx. In fact, this patient (an officer of the 68rd regiment) had been sent out to India (Madras) on this very account. He had only once been explored, however, and that very cursorily, at an Invaliding Board; nor was the aneurism ultimately proved; for no autopsy could be obtained: but the symptoms and history, together with the manner of death, left no doubt of the fact. Some weeks after this, he went to bed in his usual state, and was found dead in the morning. Of the abdominal, one eventually broke into the left side of the thorax, and yet remained undetected till revealed by the post-mortem examination. Another was mistaken for spinal disease,—bathing when over-heated with marching assigned as the cause, helped to mislead: and another for simple lumbago. Nevertheless, a more satisfactory diagnosis we have scarcely made than in abdominal aneurism. Bellows murmurs are so common, however, resembling the aneurismal, in the epigastrium, and also along the course of the

aorta, with strong pulsation, if not impulsive, that they materially interfere; though we cannot agree with those who think the murmur of pregnancy may not be distinguished from every other by its peculiar long rolling or buzzing character.

Cases.—Here we would avoid the too common error of taking our own little village to be the type of the great city, Rome; and the better to do so, may be permitted to advert to the localities and climates, in which these diseases more especially occur. In 1829, having been sent in charge of invalids from Ceylon to the Cape of Good Hope, we were there as a temporary measure attached to the 72nd, then in Cape Town, and were thus led to inquire as to the nature of the diseases peculiar to the climate.

It was said the climate is extremely healthy, and particularly on the frontier; only there diseases of the heart and blood-vessels are common, which is attributed to some peculiarity of the water. Again, at Barbadoes, in 1830, where we had gone a short time previously from England with detachments, we were in orders to proceed in medical charge of a wing of the 19th to St. Vincent, whereupon Mr. Poole, who had been there a year or two as Assistant-surgeon of the 27th regiment, remarked, St. Vincent is famous for diseases of the heart and blood-vessels, owing to the long steep ascent from the town, where the principal duties are. It is true, we were unable to prove this from the records, when at St. Vincent during the years 1848-9, or to make out, even at the period referred to by Mr. Poole, more than 1 fatal case, or 1.5 per 1000 of strength, but as these cases, at that time, seldom proved fatal in hospital, the records may not be the best place to find them, and now the strength is too small, and nearly all the town guards are withdrawn, not to speak of the comparatively short tour regiments have in the West Indies. Next we went out to Bombay, and again diseases of the heart and blood-vessels assailed us, but here it was the "abominable arrack," drunk in the Bazaars, or smuggled in by the natives. It was not, however, till at Poona, four or five years after that, that these diseases reached their acme in the 2nd or Queen's, nor were they at that time confined to the 2nd, or even to the Infantry. The fact is, they were only just then, and chiefly through the zeal of Deputy-

Inspector Collier, beginning to be fully recognised during the life of the individual. Nor must we too hastily conclude, because of their greater frequency in the East, that such is the fact absolutely. An European regiment in India is seldom under 800 strong, and almost always undivided, whereas on the Cape frontier, or even in the West Indies, Barbadoes excepted, there are scarcely 300 together anywhere. One fatal case in 200, the usual strength, would be equal to four or five in a regiment in India, and 5.5 is the highest we have known per 1000 of strength. The average, aneurisms inclusive, used not to exceed three, and now that any tendency to disease of the heart is looked for as a valid objection in the examination of recruits, a considerable diminution may be expected. It may be true, the Cape frontier, both in climate and locality, resembles many of the stations in the interior of India, but are there not other and more palpable causes, and particularly as at Poona, where the mortality from these diseases reached, the third year of the Queen's, the extraordinary ratio of 5.5 per 1,000? Poona rarely has a force of less than 4,000 men, and the scope being ample, field exercise, during the drill or cool season, are both frequent and severe; it was so at least at the period referred to, the ordinary routine being three field days a week, in addition to the usual regimental drills and parades; and these field days are much more trying to the organs of circulation than even continued but regular marching, as may be easily understood when it is considered at one time they are at "the double"—that is, running; at another, still or inactive; now half suffocated in column, and again in line, open and free to the breeze. Add to this the woollen jacket closely buttoned up, and the thick leather stock, and we can scarcely be at a loss, reasoning from analogy, to account for diseases of the heart and blood-vessels in that or any other hot climate, without the aid of peculiarities of water, long steep ascents, or abominable arrack, or even of rheumatism, as in civil life.

Prognosis.—It is rarely, as already mentioned, that cardiac and aortic diseases are traceable, among the European soldiery in India, to rheumatism; nor do they usually come under treatment at a very early period of their course. The greater number of the

cardiac prove fatal in one or two months from admission, where the valves of aorta are manifestly implicated. One or two we have known to prove fatal in one or two days; but in these venesection had been rather liberally employed perhaps, with a view to reduce the inordinate impulse. Some, on the other hand, have extended over a period of one or two years; whilst a few, having left as invalids or otherwise, have been lost sight of altogether. The most unfavourable prognostic has been the prolonged sawing murmur at the base, or abrupt and hoarse bellows at the apex; and when to either of these has been superadded an inordinate impulse, death has, in the majority of instances, been nearly at hand. The longest period we have known a sacculated aneurism of the thoracic aorta to a certainty diagnosed, was about fifteen months. This was situated near the origin of the left subclavian, and till death was only appreciable by the physical signs: pneumonia was the disease originally inferred from the symptoms alone. Three cases in particular of cardiac or aortic disease were discovered accidentally, when the patients were in hospital for other and unconnected diseases; nor had they previously complained, or even been aware, of any symptom of such. One of these was that of a man of the 17th Regiment, soon after his return from the campaign in Afghanistan. There was then no inordinate impulse, and, altogether, it appeared to be a case of very recent origin; yet hypertrophy and dilatation soon supervened, and proved fatal within the six months.

From cardiac and aortic disease we have known no case of recovery when once the prolonged sawing murmur was manifest at the base; nor have we known a single patient to be alive, except one of the growing boys already alluded to, at the end of two years; and therefore have little to recommend in the way of treatment. Venesection, however, is especially to be avoided, and all remedies of a directly lowering nature. Temperance in all things, quiet in the most extensive sense of the word, and loose clothing, will be readily suggested to every one; and, if to these means be added a few leeches occasionally, and such other moderate remedies as may from time to time become necessary for the relief of urgent symptoms, or of secondary diseases, as hepatitis,

pneumonia, or dropsy, it is the utmost, perhaps, medicine can effect. Mercury, as in the rheumatic disease, if at an early stage of its course, might possibly do good, or sarsaparilla with the iodide of potass.

Bristol, Oct. 11, 1850.

N.B.—It is not meant that the above diseases are confined to the non-commissioned, nor can we say absolutely that they are even more frequent in that class; for, owing to the comparatively small number of officers in a regiment (30 to 35 actually present in India) it is not easy to determine the point. Many officers, too, have an aversion to being stethoscoped, as it is called, when labouring under any cardiac symptoms, whether it be functional or organic. One in particular (no doubt of the former class) could not even see the instrument approach the region of the heart without becoming sick or faint (the same thing we have seen in dyspepsia on pointing the finger at the stomach); and another, the late Assistant-surgeon of the 6th, or Royal Warwickshire, would not, because (as he said) he was sure it was organic. This was at Poona, in 1840; and, by the newspapers, we observed he fell suddenly dead at Chatham the following year, a few days after he reached England with his regiment.

In none of this class either in India could the disease be traced to rheumatism. Only one admitted "lumbago," a short time before the cardiac symptoms commenced. In two, however, it was the simple hypertrophy, loaded with fat, with enlarged liver, &c.; and one perhaps was congenital; but neither would this submit to an exploration, and at last he died dropsical away from head-quarters.

NEW TEST FOR THE DETECTION OF SULPHATE OF QUININE. BY M. VOGEL, JUN., OF MUNICH.

WHEN a concentrated solution of ferrocyanuret of potassium and a few drops of chlorine are added to an alcoholic solution of quinine, the liquid assumes a clear red colour. If the solution of prussiate be not concentrated, the addition of a few drops of ammonia will produce the tint. The same test is applicable to dry quinine. No other organic base produces the same effect, according to M. Vogel: this test may therefore be relied upon for the presence of quinine.—*Journal de Chimie Médicale*. x

ON THE
OCCURRENCE OF STARCH GRA-
NULES IN THE URINE,
AND ON THE MICROSCOPIC EXAMINATION
OF THIS SECRETION.

BY THOMAS INMAN, M.D.
Liverpool.

MR. BALMAN, in a recent paper in the *MEDICAL GAZETTE*, p. 799, draws attention to the fact that starch granules are often found in urine, and mentions one case where they were abundant enough to form a distinct deposit visible to the naked eye.

I can corroborate his statements respecting the frequency of the presence of granules, and his observation that they consist usually of wheat starch. The fact is one of considerable interest. It is, I think, almost self-evident that they must exist in the urine accidentally, and must be introduced into it subsequent to its passage from the bladder.

We may imagine many ways in which they may be so introduced; the most common is probably the following:—Bread being an universal article of diet, its crumbs are to be found in every house. Falling on the floor they harden, get trodden to dust or powder. When the floor is swept or the foot passes over, the dust rises, and part gets deposited on the internal surface of all the chamber utensils, and of every unclosed bottle. Urine is voided into its usual receptacle, and poured thence into a bottle for examination, and is then found to contain wheat starch.

That such is occasionally the case I may illustrate by the following observation:—

The urine of a young man who had signs of a morbid growth in the bladder was given to me for microscopic examination. In it I detected a very minute white mass, like a flake of lymph. It consisted apparently of a number of indistinct reticulations, and a number of cells which closely resembled in their general aspect some animal formations. Alas! I saw one which had an appearance as like boiled wheat starch that I applied the test of iodine. I then found that all were turned blue, and that the fragment was therefore a piece of bread or biscuit accidentally introduced.

When the quantity of starch is as great as that described by Mr. Balman in the case he narrates, we must suppose that the patient introduces it in some way, either accidentally or with the intention to deceive.

I may add, in corroboration of the idea that in no case can the starch be a urinary product, that this fluid will entirely dissolve when added to a hot solution. It would equally prevent the formation of the granules.

While on the subject of the urine, I may mention a curious observation I made a short time ago on a specimen sent me for examination. When first seen it contained nothing beyond cubical crystals of oxalate of lime, which existed in immense numbers. Next day more than half of these had disappeared, and their place was taken by stellar and prismatic crystals of the triple phosphate.

As the phosphatic and oxalic diathesis are supposed to be closely allied, the apparent conversion of one deposit into the other out of the body is particularly interesting.

I scarcely need add that the power used was a $\frac{1}{4}$ inch of Powell's, that there was no mistaking the one set of crystals for the other, nor was there any opportunity for any practical joker to change the contents of the bottle.

INDURATION OF THE STERNO-CLAVO-MASTOIDEUS MUSCLE IN YOUNG INFANTS.

Communicated by T. B. CUMMINGS, ESQ.,
Surgeon to the London Hospital.

WHILST I had charge of the out-patients at the London Hospital, infants a few months old were occasionally brought to me on account of stiffness of the neck, which I found to proceed from a remarkable induration of the sterno-clavido-mastoides muscle on one side. The muscle was in all cases well defined, and felt rigid, and almost of cartilaginous hardness. I have preserved notes of four cases, in all of which the muscle affected was the left. The affection did not appear connected with any derangement in health, or to produce any inconvenience beyond the stiffness alluded to; but this, coupled with the hardness, was sufficient to excite some alarm in the minds of the parents. I do not recollect having met with any instance of it later than ten weeks after birth, and generally the infant was about three or four weeks old. In the last case that I saw, which was sent to me by my colleague Dr. Frampton, the child was aged seven weeks. The induration invariably subsided very gradually. The treatment resorted to was the application of a mild liniment and a grain or two of the Hydrargyrum c. creta.

I have had no opportunity of ascertaining the structural character of this curious muscular affection, nor of determining its cause; but, from the early age at which it occurs, and ultimate subsidence without impairment of the part, I suspect that the induration was consequent upon some injury to the muscle at birth, producing a chronic deposition of lymph between the muscular fibres. I have inquired of several experienced accoucheurs, but I found they were unacquainted with the affection, and unable to account for it.

NATURAL HISTORY OF THE CINCHONAS— THEIR GEOGRAPHICAL DISTRIBUTION.

THE geographical distribution of the Cinchonas, according to M. Wedell, extends from 19° south lat. to 10° north lat., and forms a large arc of a circle, having its convexity turned towards the west, its most western point being about 4° S. lat. and 80° W. long. (merid. Paris), its northern

extremity being in 69° W. long., and its southern extremity towards 65° W. long. The width of the zone varies in different parts, and gradually diminishes towards each extremity. It was observed that beyond a certain altitude it became confounded with the belt of forest, and ceased with it.

The Cinchonas abound most on the eastern slopes of the Andes, the western sides of which are almost without wood. The streams which water the regions of the Cinchonas are, with small exceptions, the tributaries of the Amazons, with some of those of the Orinoco. According to preceding travellers, the height at which the Cinchonas vegetate is from 3956-00 to 10725-60 feet above the level of the sea, and the mean height of their limit is between 5248-00 and 7872-00 feet.*

M. Wedell having closely watched the growth of the Cinchona, and the process of development of the bark, divides the latter into two kinds—the outer, or more fibrous portion, and an inner, or cellular portion. The latter he states is full of quinine, the former in cinchona. M. Wedell makes, however, this distinction,—that it is not in proportion to the amount of cellular tissue that the quinine is abundant, but that the bark is rich in quinine in proportion as the cellular and fibrous tissue is intermingled. The most favourable combination appears to be a certain distribution of the fibres among the surrounding cells, which are filled with resinous matter, whereby each fibre is, as it were, isolated, or they are separated by thin laminae of this cellular structure. The fracture of a specimen indicates the character: when the cellular tissue predominates the fracture resembles that of cork; while in the fibrous variety the fracture is characterized by numerous points and filaments.

M. Wedell states, also, that he has every reason to believe that the root possesses the same properties as the bark.

M. Wedell has reduced the number of species of Cinchonas from twenty-four, the usually received number, to eleven. To these, however, eight hitherto unknown species must be added.

M. Wedell attributes the varieties of Cinchona met with in commerce to differences in their age, exposure, &c., as they may all be produced from one tree.—*L'Union Médicale.* X

* The highest of the Andes,—the Nevada de Sorata, in Bolivia or Upper Peru, is said to be 25,350 feet, or nearly five miles, above the level of the sea. The next highest of these mountains is Illimani, in Peru, the summit of which exceeds 24,500 feet.

The line of perpetual snow in the equatorial regions of South America is at the height of 18,500 feet.

MEDICAL GAZETTE.

FRIDAY, NOVEMBER 23, 1850.

Among the Blue Books which have been lately issued, there is one which possesses considerable interest in a medical point of view. We allude to the Report of the Select Committee of the House of Commons on Prison Discipline. The facts and opinions therein contained, having reference to the effects of separate imprisonment on the mental and bodily health, are so important, and in some respects so unexpected, that they demand, and will no doubt receive, serious attention.

It is a commonly-received opinion with the public, as well as among members of the medical profession, that separate confinement cannot be inflicted upon prisoners without inducing greater evils to body and mind than are consistent with justice, or than are counterbalanced by the good which may result, in a reformatory point of view, from so severe a punishment.

An examination of this Report will, we think, serve to remove this impression by showing that separate imprisonment is perfectly compatible with good health, and that it is even attended with an immunity from disease not to be found in many honest callings. It demonstrates, moreover, that separation is a system more favourable to, and more positively productive of reformation, than any other mode of punishment. It is not, however, our purpose to intrude upon the province of the moralist or the jurist: * we shall

* For information upon the punitive and reformatory fruits of the "separate system," we must refer our readers to the facts stated in evidence before the Committee; to the yearly Report of the Commissioners of Penitentiary Prison to the letters received from convicts in the Colonies; to a work entitled, "Prisons and

confine our observations to those parts of the Report which have a medical bearing. These may be arranged under three heads:

1. *Opinions in which the separate system is regarded as unattended with excessive injury to the mental and bodily health.*

2. *Opinions in which it is considered to be inevitably attended with excessive injury to body and mind.*

3. *Facts by which the separate system is shown to be free from excess of danger to body and mind, and thus a perfectly safe form of punishment.*

1. *Opinions in which the separate system is regarded as unattended with excessive injury to mental and bodily health.*—These are, to be found, repeatedly and confidently expressed by statesmen of the highest integrity; by legislators who have devoted time and earnest attention to the subject of prison discipline in all its varied forms; by governors of prisons, both upon the separate and under other systems; by chaplains, who declare that they find it to be the only machinery that holds out a prospect of reformation; and, lastly, by medical officers, who have watched its working, and have not only not detected any injury to the minds and bodies of prisoners as its result; but have even found it to be in some cases beneficial to the health.

The verification of all these statements would carry us beyond the space which we can spare to the consideration of this first division of our subject; but proofs will continually appear in the facts to be subsequently brought forward. We observe, however, that at a period when the merits of the separate system were only beginning to be developed, the late Sir Robert Peel thus

expressed," written in
Chambers to Penit

ingramm,

own
old.

embodied the result of his investigations on this subject, in the preamble to a bill which he introduced into Parliament in 1843:—"Due classification, inspection, separation, regular labour and employment, religious and moral instruction, are essential to the discipline of a prison, and for the reformation of offenders."

Most politicians have arrived at the same conclusions;* and the last authoritative exposition of the kind comes from the Committee whose Report is before us, and which we here quote:—

Resolved,—“That this Committee concurs in the opinion that entire separation, except during the hours of labour and of religious worship and instruction, is *absolutely necessary* for preventing contamination, and for securing a proper system of prison discipline.”

Up to the end of the year 1847, the Reports of the Medical Commissioners of Pentonville Prison had confirmed the opinion that the health of prisoners suffered no damage, or that any evil possibly consequent thereon was counterbalanced by its alleviations. These reports being confirmed by those of the surgeons of convict ships, who removed the prisoners to the colonies, are entitled to some respect, but they are still more deserving of notice, when it is considered that they are the results of Sir Benjamin Brodie's observations for six years, of Dr. Fergusson's also for six years, of Dr. Bisset Hawkins' for a shorter time, of Mr. Green's for two and a half years, and of Dr. George Owen Rees's daily superintendence and visiting during a period of seven years.

Mr. Hampton, surgeon superintendent of the “Sir George Seymour,” who took out 345 prisoners to the colonies, speaks in high terms of commendation

of the men, stating that their bodily health was good, and “their intellect in a more vigorous and healthy condition than in any prisoners he had previously observed.”

Mr. Baker, surgeon superintendent of the Stratheden, remarked, that the prisoners from Pentonville “were in excellent health, more so than the sailors of the ship, and that in his opinion they were healthier than the same number of men out of a man-of-war would have been: they were as active and intelligent men as ever he saw.”

Abundant additional testimony to the same effect might be adduced from similar sources. This testimony is accessible in the Report with which we are now concerned, and in the yearly Reports of the Pentonville Commissioners.

2. Opinions which regard separate imprisonment as inevitably attended with excess of injury to body and mind.—In the present volume of evidence these do not bear any proportion to those of an opposite character. Even among most of those adverse to the system, their conclusions have reference rather to the time during which it can be safely borne, than that it is altogether unendurable. This view of the question will be shown in our subsequent observations to have been also definitely settled; and, moreover, it will be shown from the facts elicited at Pentonville Prison (which we may here state we shall assume as the basis of our comparisons), that the question of the time for which the system may be applied is the most important of any involved in the discussion.

We take the Pentonville Prison as a basis, because it is the “Model” prison in which the “great experiment” (as it has been justly designated by Sir James Graham) of modified separation has been reduced to practice; and we shall show that the experiment has been

* They have been embodied in a Report by a Committee of the Lords on Prison Discipline in 1835.

successful, or at all events that it was so in the earlier years of the trial.

It may here be noticed that the separate system as exhibited in the Model Prison at Pentonville, must be kept distinct in the mind from the solitary system as at first adopted and practised in America; and from the separation which (with less efficient alleviations than at Pentonville) is put in force for short periods in some other prisons of England.

It is obvious that the comparison of the effects of separate confinement on body and mind must be different among prisoners confined for a like period, part of whom are undergoing the punishment as the first term of a long period of transportation, and a similar number undergoing the same period as their entire punishment.

It must also be borne in mind, that before the conclusion can be arrived at that the discipline of any particular prison is productive of ill effects to the health, over and above that of any other prisons, it is highly necessary that all conditions be ascertained to be similar. For instance, it must be known whether the diet be equally good, whether the situation be equally salubrious, and whether the physical condition of the prisoners be the same; thus the results obtained from the observation of prisoners consisting of agricultural labourers cannot be the same as those compared with a prison full of low London or Manchester thieves and pickpockets. Much difference will be found in the two cases; but this is explicable on other grounds than the effects of the system.

The following extract from an article in the Quarterly Review, for December 1847, well expresses the light in which the system should be viewed:—

“What are the effects of such a system of discipline? Quite innocuous,

say some; madness or premature disease, say others. Both opinions are partial. It is hardly to be expected that an individual can fail to suffer when he is at once imprisoned in body and constrained in mind. On the other hand, those who have designated prisons on the separate system as ‘manufactories of madness’ have probably confounded the solitary with the separate system. In France, Esquirol, and other high authorities on mental diseases, have asserted that the latter system has no tendency to deteriorate the mind; and, as far as a five years’ experience of the working of discipline at Pentonville has gone, close observers coincide with them.”

We would refer those of our readers who may be disposed to take an interest in this subject, to this article in the “Quarterly,” as being a masterly exposition of the whole question, attributed to the pen of one well qualified, by his thorough knowledge of the subject, to offer a trustworthy opinion. As a review of the results of the trial of the earlier system of long periods, this article supplies valuable evidence to the effect that separation is unattended with injury to bodily and mental health. It is shown from statistics that the prisoner in Pentonville suffers no more, or that his mortality is no higher, than that of the soldier in the choicest spots of the Mediterranean, or in the bracing climate of Canada. We quote again on this point:—

While the annual mortality at Pentonville is (in 1847) 15·70 per 1000, that of the Foot Guards is 21·0; nay, the mortality from consumption alone in the Guards is nearly as high (14·1 per 1000) as the total mortality of Pentonville prisoners—men, be it observed, of about the same age, on an average, as soldiers.

“At Pentonville, then, the daily ratio is 14 sick in 423, or about 33 in 1000. In the Prussian army the daily average is 44 per 1000. Among the British Dragoons, and Dragoon Guards, 44 per 1000.”

We find three different modes adopted at Pentonville in calculating the mortality of the prisoners:—1. The actual mortality—i. e., the number of deaths. 2. The actual mortality, to which are added three-fifths of the medical pardons as a fair proportion to be allowed for the deaths that would have ensued from the diseases which formed the ground of pardon. 3. The mortality, including the *whole* number of medical pardons. This will give too high an estimate, as many pardoned on medical grounds have been known to recover. In the first case we find the mortality to be, in round numbers, about 6 per 1000; in the second, about 8 per 1000; in the last, about 14 per 1000. The entire prison population showed a mortality (from 1838 to 1842) of about 19·62 per 1000, according to the calculations of Dr. Baly, physician to the Millbank Penitentiary.

We have noticed, in going over the evidence in this Report, that the witnesses who expressed themselves most decidedly on the injurious influence of separation did not support their opinions either by positive or negative facts.

Thus Dr. Baly, in answer to the question whether separation shows itself more injuriously at the commencement than at a more lengthened period, answers—"I cannot lay down any rule as to the period at which the mind becomes affected by imprisonment. As regards the bodily health, the longer the imprisonment is continued, as far as the end of three years, the greater is the effect; but as regards the mind there seems to be no precise rule. Many prisoners suffer in their minds at an early period; others, and I think more, at a later period; but there is no great difference in the proportion at the two periods."

Now we cannot but suppose that, if an uniform cause be in operation, the

effect will be uniform, and that there will be a "precise rule" discoverable:—with regard to Pentonville, this has been shown in the tables we shall subsequently quote.

Again, Dr. Baly states—"A great many prisoners going to Millbank from separate imprisonment have suffered in their health; some as invalids, some as incorrigible, some in bad bodily health, others disordered in their minds." But at the same time the relative periods for which they had previously undergone rigid imprisonment under the separate, and under the other systems, are not stated. It cannot be doubted that facts, in the shape of the actual numbers thus asserted to have suffered, would have been most desirable.

Captain Groves *thought* that prisoners under separation were in worse health than those in association; but adduced no facts in support of his opinion.

Captain Macdonochie, allowed that "separation is a very good servant, but a very bad master;" but that "it is very desirable to have a separate apparatus." His objections to the separate system, as a mode of punishment, were founded on its trial by himself on twelve prisoners for the longest period (in one case only) of six months. Of the moral conditions under which this experiment was made we are left in ignorance.

The evidence of Captain Whitty, Governor of Portland Convict Prison (to which the Pentonville prisoners are removed) was not more precise. We quote portions thereof:—

Q. "In what state, mentally and physically, do you generally find those prisoners that are brought under your care when they come from separate confinement?"

A. "Latterly they have been much improved in that respect. In the first instance, when the prison was established, I think many came to us from

separate confinement in a very reduced state from some of the prisoners."

This witness then deposes that the prisoners recover their health and spirits after removal to Portland—"all of them improve in health and cheerfulness." On this topic the following examination ensues:—

Q. "Then you find that, though in 1849 the mental and physical depression of the prisoners was not so great as it was during the early period of your government, still all the prisoners do come to you mentally and physically depressed?"

A. "I have observed that, to a certain extent, the prisoners are in a state of physical depression when they come, but I should not like to undertake to say that they are in an actual state of mental depression."

Q. "You stated, in answer to a former question, that you observed a change in the prisoners in regard to their cheerfulness, after they have been under your care for some time?"

A. "Yes."

Q. "Do you infer from that fact that there was a degree of mental depression at the time that the prisoners came under your charge?"

A. "Yes: a degree. That is what I meant to say just now."

Few persons, we conceive, would give to the above evidence a higher rank than that of mere loose opinion, the result of casual observation, and not of close examination on the point referred to. We cannot attach a more definite character to this witness's statements in reference to the bodily and mental effects of separation.

The influence of the separate system in producing or developing phthisis has been much dwelt upon. That an excess of phthisis did appear in some years at Pentonville prison was admitted by Dr. Rees, who traced it to the dusty trades taught to the men in their cells. On the adoption of proper measures the mortality from this cause, as we have observed in a former number of our journal, suddenly abated

We shall take an early opportunity of returning to this subject.

CONCLUSIONS REGARDING THE ELIMINATION OF IODINE BY THE KIDNEYS.

DR. DALTON, of Boston, has drawn the following conclusions from his researches on this subject:—1. After a single moderate dose, iodine may appear in the urine in so short a time as thirty minutes, and continue to appear for nearly twenty-four hours afterwards. 2. After a much larger dose, taken habitually for a long period, the time necessary for complete elimination is not proportionally increased. 3. It is therefore probable that iodine, or at least iodide of potassium, does not accumulate in the system in any considerable quantity; and it is questionable whether a large dose, taken habitually, produces any more constitutional effect than a moderate one, since the superfluity is constantly removed by the kidneys. 4. The colour, produced by the reaction of starch with urine containing iodine, varies, according to circumstances, from a light purple, slaty-blue, or French gray, to deep indigo, or absolute black. 5. A solution of iodide of potassium in distilled water, in the proportion of one-eighth of a grain to the ounce, produces, with starch and nitric acid, an opaque black colour, as strong as is ever observed in urine. A solution in the proportion of one-sixteenth of a grain to the ounce produces a strong purple, moderately translucent. 6. It is therefore probable that iodide is often excreted in the urine in about as large a quantity as one-tenth of a grain to the ounce; since one-eighth of a grain of iodide of potassium contains nearly one-tenth of a grain of iodine.

Iodine is usually perceptible in the saliva at the same time that it appears in the urine; but it does not always exist in these two secretions in the same proportions. Thus, in one instance, the urine showed only a faint purplish colour by the reagents, while the saliva exhibited a strong blue. The same or even greater irregularity was observed by Dr. O'Shaughnessy in the case of the dog above referred to, since the poison was abundant in the saliva on the third day, but could not be detected in the urine: on the fourth and fifth days, however, it again appeared in the latter excretion. Becquerel (p. 128) speaks particularly of these occasional variations, and acknowledges that we cannot, at present, refer them to any fixed law.—*American Journal of Medical Sciences* for July, 1850.

Reviews.

Contributions to Mental Pathology: with Introductory Observations: containing the Past and Present State of the Insane at Ceylon, &c. By JAMES GEORGE DAVEY, Licentiate of the Royal College of Physicians of London, &c. &c. 8vo. pp. 276. London: Churchill. 1850.

NEARLY one-third of this volume consists of a narrative of the annoyances to which the author was exposed in the performance of duties for which he was sent out to Ceylon by Lord Stanley. Dr. Davey seems to have been placed in a false position, and, according to his own account, to have been extremely ill used; but in this, as in all quarrels, something may probably be said on both sides: we shall therefore not dwell on this point.

The remainder of this work comprises three reports on the State of the Lunatic Asylums in Ceylon, presented to the Colonial Government. These reports, unfortunately, also include much of the correspondence between their author and the Colonial authorities with respect to the measures which it was indispensably necessary should be adopted for the amelioration of the condition of the insane in Ceylon, which was as bad as bad could be.

A few extracts will put our readers in possession of the author's pathological views with reference to insanity.

"We have employed the words 'mania,' 'melancholia,' 'monomania,' &c. &c.; and we have done so, not because we consider their use in the least degree calculated to elucidate the various abnormal phenomena of the mind, but for this reason—the want of a correct and classical nomenclature of mental diseases. No person, unless he be a phrenologist—that is, unless he is well acquainted with the functions of the brain in a state of health—can possibly be a good judge of the indications of an unsound mind" (p. 90).

On this dictum of the author it is possible that there may be two opinions. For our own part, we altogether decline accepting the proposition otherwise than as an assertion the *onus probandi* of which lies with Dr. Davey.

We do not consider that the case given below furnishes conclusive evidence of

the therapeutic action of Mesmerism. Our readers do not require to be informed that insanity, epilepsy, and apoplexy, are not unfrequently combined in one subject, and that the symptoms of either form of disease may precede the other, and subside to give place to those of a fatal character.

"We feel we should be guilty of great and unpardonable neglect, and moreover incur, and deservedly too, the censure of the man of science and the philanthropist, if we were to allow this opportunity to pass without insisting on the remedial efficacy of animal magnetism, or mesmerism, in cases of epilepsy combined with mental disease. Since our connection with Heddelle, we have succeeded in restoring one poor native lad to perfect health who, for a period of, we learn, seven years, was afflicted with epilepsy of the most distressing character. He used to have from two to five fits per day, and each one was commonly so severe as to leave him for some time more or less insensible. His appearance when first mesmerised was exactly that which belongs to the last stage of phthisis, so emaciated was he. Three months after we commenced our operations, not only had the fits entirely left him, but he then presented the appearance of robust health, and had become stout and really muscular. The case created a great sensation among the servants, whose remarks upon it were not a little curious. When on the eve of obtaining his discharge he was attacked with apoplexy, and died about thirty hours after" (p. 98).

It is a question that may fairly be asked, Why Dr. Davey, being a believer in mesmerism, did not ascertain beforehand, by the means of clairvoyance, whether there existed in Ceylon any obstacles to the fulfilment of his mission such as he has put on record in this volume.

The following severe criticism on the opinions of some of the highest legal authorities of the present day seems to suggest the possibility that the manner as much as the object of Dr. Davey's performance of his duties in Ceylon may have given offence to his professional brethren holding high offices in that island:—

"The judges of the present day, like those of the olden time, persist in declaring all persons to be *sane* and *responsible* who can distinguish *right* from *wrong*. Lord Hale's dictum continues yet to influence both our legislators and lawyers. The bar and the bench alike continue to grovel

in the mire and obscurity which characterizes the public acts of such men as Mansfield, Erskine, Denman, Abinger, and Follitt, as shown on the trials of Bellingham, Hatfield, Oxford, Blacklesley, and M'Naughten, to which the reader is here referred as an illustration of the false reasoning employed by the legal profession in matters relating to the question of insanity.

"I would beg leave to introduce to the reader's attention the following extracts from my medico-legal reflections on the trial of Daniel M'Naughten" (p. 120).

The last paragraph stands in unhappy proximity to the unqualified charge of ignorance fastened on the judges of the land by the author. Dr. Davey would have the responsibility of lunatics determined by phrenology, and observes, "that the sooner the LAW OF LUNACY is blotted from out the statute-book of the empire, so much the better for the law and lawyers; and if not for it and them, for Ransom and Henshaw's sake" (p. 120).

But, with all due deference to Dr. Davey, we may repeat what has been said on another occasion:—

"It is justly supposed, from the experience and knowledge which the members of the bar must acquire before they are promoted to the judicial bench, that there are no men better qualified than our judges to interpret the laws of this country."

Beyond the author's phrenological and meager opinions, a good account of the treatment adopted at Hanwell, and the topics of local interest to which we have already alluded, we have found but little in this volume to justify our recommendation of it to the notice of our readers.

An Introductory Lecture, delivered at the Massachusetts Medical College. By HENRY J. BIGELOW, M.D., Professor of Surgery in Harvard University. Pamphlet, 8vo. pp. 52. Boston, U.S.

An interesting discourse, pointing out the mode in which surgery should be studied, and the errors of surgeons avoided. The fashionable quackeries of the day are noticed, and their sources traced. In the exposition of all the varied topics which are embraced in this Lecture, a thorough knowledge of surgical science is seen to be combined with great command of language and extensive literary acquirements.

* See editorial observations on the case of *Nottingham versus Bigelow*, *Mass. Gaz.*, N. S., vol. ix. p. 1061.

The Unity of Nature. By CHARLES BLAND RADCLIFFE, M.R., &c., Lecturer on Vegetable Physiology and Botany at the Westminster Hospital, &c. 8vo. pp. 150. London: Churchill. 1859.

THE analogies observed between the varied forms of organization have afforded to men of speculative turn of mind the data whence they have deduced the laws of the unity of nature, and the facts on which they found the science of transcendental anatomy. An extensive acquaintance with the structures both of animal and vegetable life is demanded for the successful pursuit of this branch of science, and is doubtless possessed by those whose names stand foremost among its cultivators: we need only mention those of Owen, Macleise, Oken, and Cuvier, with whom we think may now be joined that of Radcliffe.

Dr. Radcliffe has arranged his subject under the two chapters of *unity of form*, and *unity of force*. In the first, the unity of form to be observed in the general plan upon which the several organs of plants and animals are constructed is treated; then the uniformity to be observed in the entire organism. Unity of form is next traced between the plant and animal. By transferring the author's words on this point to our pages we shall afford our readers an opportunity of judging of the general character of the work before us.

"1. In the perfect plant, the arrangement of parts in a spiral, branching, or radiate manner, together with the absence of the power of spontaneous movement, may be considered as general and universal features of organization. The presence of such characters, indeed, is involved in the very idea of a perfect plant.

"2. In the animal, also, we may always discern branching, radiate, and spiral tendencies in the plan of organization. The power of spontaneous movement, which is the attribute of the higher forms of animal life, may seem, indeed, a fatal objection to the analogy of the plant and animal; but this objection is only apparent. Such a power cannot be deemed characteristic of every animal form: indeed, in the earlier periods of the history of the nobler creatures,—which epochs are typical of vegetable life,—and in myriads of forms belonging to the radiate and molluscous provinces of nature, where the plant-phases of the embryonic state of the higher animal, are permanent conditions of being, not only

is there an absence of the power of spontaneous movement, but the animal is actually a prisoner like the plant. . . . The parallelism of the animal to the plant, in the general characters of the organic plan, is seen, however, more distinctly, if we travel successively through the several ranks of being." (p. 47.)

If our readers have any love of the science of anatomy and physiology, they may profitably follow the author.

The points of resemblance which can be discovered in the general features of organic and inorganic nature are fully set forth by the author.

Under "Unity of Force," which constitutes the second division of his subject, Dr. Radcliffe touches upon Mr. Grove's exposition of the "Correlation of Physical Forces," and quotes several of Mr. Grove's illustrations. In speaking of "the phenomena in vital force," the author dwells upon the nature of man, his original character, his present fallen condition, and his future destiny. We think Dr. Radcliffe ventures on dangerous ground in attempting a definition of the humanity of Christ:—

"If we take the highest possible degree of life, as manifested in Christ, we may understand that there is no absolute distinction between the material and sensible humanity and the supersensuous principle." (p. 145.)

We most cordially accept the following declaration of the possession of the best founded principles of belief:—

"I am unhappy if I give the readers of these pages any wrong impression of my opinion in these matters. Far be it from me to wish to degrade any sacred and sublime mystery into a mere philosophical abstraction; and though I would hold forth as a truth essential to the interpretation of the phenomena of vitality, the fallen position of man, yet I would never forget that the Godhead of Christ is absolute and infinite, and that to this, our own being, though congeneric in essence, can never hold a higher relation than that of finite to infinite, or of created to Creator." (p. 147.)

As in the writings of Professor Owen, so in Dr. Radcliffe's work, we find, as we have shown, an avowal of a believing submission to the sacred record of creative power, in all points that are beyond the reach of finite human knowledge;—and in this subject we would claim for the writings of our countrymen a higher character of simplicity

and intelligibility than is possessed by those of our continental brethren. Dr. Radcliffe's explanation (above quoted) is certainly more intelligible than the strange and complicated formulæ of Oken, the most striking characteristics of which are their obscurity and irreverence. We may here cite a few short passages in support of our position. Oken, in his "Elements of Physico-Philosophy," states—

"God is a rotating globe." . . . "The world is God rotating." . . . "God is = + O —. Man = + ∞ O — ∞. The animal = + m N — n."

This may be, physico-philosophy; but it strikes us as very like what, by an inspired writer, was termed "philosophy falsely so called."

We can truly commend Dr. Radcliffe's essay as full of interest, sound in its inferences, and calculated to enlarge our ideas of the vastness and simplicity of the schema of creation, while at the same time it tends to increase our reverent admiration of the Omnipotence and Omniscience which, amidst such apparent incongruity, has established harmony, and has so marvellously combined unity of plan with endless variety of details.

On the Management of Infancy; with Remarks on the Influence of Diet and Regimen, &c. By CHARLES HOGG, M.R.C.S., L.A.C., &c. 8vo. pp. 132. London: Churchill. 1850.

ALTHOUGH the observations contained in this work must be admitted to be judicious, and calculated to be useful to junior practitioners, it certainly has but small claims to originality: in fact, it consists, to a very considerable extent, of extracts from numerous writers. In addition to the management, diet, and regimen of infants, the subjects of cutaneous eruptions, struma, and hepatic disorders, with their treatment, occupy more than half of the volume. In looking over the cases we do not perceive that their treatment varies much from that which the recognised principles of medicine would dictate. From the style of the preface, and of the work itself, we should infer that this work is rather intended to meet the public than the professional eye.

* Translated for the Bay Society, pp. 132-133.

Address to a Medical Student. Second Edition. 16mo. pp. 107. Oxford: Parker. London: Churchill, 1880.

It is not long since we had the gratification of bringing under the notice of our readers part of a series of Biographies of Eminent Christian Physicians, edited by Dr. Greenhill, in which the truth of the adage, "example is better than precept," was strongly corroborated. This proverb, however true, does not lead to the inference that precepts are unnecessary. That the reverse is the fact is sufficiently attested by the copious body of precepts composed and collected by the wisest of men, who taught therein that "He that hearkeneth unto counsel is wise" (Proverbs xii. 15). Having, then, on that occasion spoken of examples, we now take occasion to draw attention to this small volume of "precepts."

The "Address to a Medical Student," which is deservedly dedicated to Dr. P. M. Latham, is published at an opportune time, although the first of October for 1880 has passed away. The term of *Studentship* has only just commenced to many, and been renewed to others with the present season. The first of October has been called, by a popular writer, "a great day with the doctors;" but that writer does not tell his readers how great it is, and that, in truth, it is really very little greater than any other day which follows it to all who undertake the responsibilities, the trials, and the anxieties of a medical life. The Address before us does this in the clearest manner; and, in the most earnest words, it reminds him that, whether he will hear or whether he will forbear, the medical student enters upon no trifling or easy undertaking at this time. This little book sets before him "a plain and simple view of the profession upon which he is entering, its difficulties and its dangers, no less than its pleasures and its advantages, and reminds him by WHOSE aid alone he can be enabled to keep himself unhurt by the temptations which will assail him."

We would advise attentive perusal of the introductory observations, instead of a cursory glance thereat, according to common fashion. The second chapter treats of the "choosing a profession,"—one of the most important actions in a young man's life. Under this head the author offers suggestions to assist the student in answering the only ques-

tion that he should put to himself with reference thereto—"Is this the state of life unto which it has pleased God to call me?" It would be better for the profession if this question were deliberately weighed by students in every aspect in which the author places it. There would be less of disappointment, and a more conscientious performance of our obligations, if it were so. If entered upon in the proper spirit, and under the influence of a conviction that the physician should regard himself as God's servant, having before him the example of our Saviour, who, when in the "form of a servant," took the physician's character,—if sincerely entered upon, and carried out with this feeling, "how welcome would be the toil, the carefulness, the want of ease, the broken rest, of the doctor's life!"

The following passage in reference to particular branches of the profession deserves attention in these days of class contentions:—

"I would only beg you to remember, that, though the physician is by law at the head of the profession, yet, in God's sight, he enjoys no such superiority of rank; for each branch of the profession is equally useful and necessary to mankind; and we may believe that in His eyes there is no distinction, except 'between the righteous and the wicked, between him that serveth God, and him that serveth *Him* not.' In fact, both in a scientific and a religious point of view, it seems to me that a *perfect* specimen of a general practitioner would be the noblest member of the whole profession. In a scientific point of view, from the fact of their combining both medical and surgical practice, and from other circumstances, the members of this branch of the profession enjoy several advantages over both physicians and surgeons, which I suppose nothing but their (in too many instances) inferior education prevents their turning to better account."

There can be but little difference of opinion on this view of the case, except from the difficulty in the present day of defining a "*general practitioner*." We must quote also the following passage, to which we would draw the especial notice of practitioners as well of students, as, from our experimental knowledge, we cordially testify to its truthfulness:—

"When you have determined on the branch of the profession to which you will belong, you may perhaps have another im-

portant question, to decide—viz. whether your medical career shall be exclusively practical, or whether it shall be entirely scientific or literary (but still professional), or whether you shall endeavour to combine in some measure both these characters . . . only I would say, that, as our intellectual faculties ought to be cultivated to the utmost extent, *that man seems to me to be most highly favoured by God who is allowed to find time not only for active employment in healing disease, but also for the cultivation of his own mind by study; perhaps, too, for imparting the results of his learning and experience to the young, or for writing some work that may be useful to his own or to future generations; or, in other words, that he approaches more nearly to the idea of a perfect physician who combines literary or scientific knowledge with practical skill, than he who gives himself up to the exclusive pursuit of either.*"*

With a reasonable amount of energy, and a will so to do, the way may in every case be found to create the combination here spoken of. The busiest man has spare minutes and quarters of hours during his rounds, or in his leisure, during which he may pursue his own or others' literary improvement if he be so determined.

The hospital, the dissecting-room, the lecture-room, daily life, and the examination, each furnish topics of exhortation, advice, and of encouragement from Dr. Greenhill to the medical student. Not only, we may observe, to the student, but also to the advanced practitioner, who may here hold up the mirror to himself, and view therein his past shortcomings, and from the self-reproachful retrospect derive lessons of future improvement.

This little work is indeed a compendium of the best advice, most judicious caution, most excellent inducements, and highest motives. The author's only object "has been so to direct the studies of the younger members of the profession as to make them Christ's true servants—is short, *good* physicians, in the highest and best sense of the words."

In concluding our notice of this interesting and eloquent address, we would here state that Dr. Greenhill has, at his own cost, undertaken the editing of a series of works touching the ethical and religious relationship of the profession; and we cannot but hope that, for the

honour of God, for the sake of the charities to which the profits of their sale are appropriated, for the sake of Dr. Greenhill's own resources, which alone meet the expenses and risk of publication, and for the lasting benefit of our profession, that these works will be sold extensively and studied diligently. Lastly, we trust that we may ere long have to announce the publication of a complete code of medical ethics from the pen of one so able to compose it in conformity with the morality of Scripture and the requirements of the profession, as Dr. Greenhill.

Instruction in Chemical Analysis (Qualitative). By Dr. C. F. GREENHILL. Edited by J. L. BULLOCK, Fellow of the Chemical Society, &c. 3d edition. pp. 384, 8vo. London: Churchill. 1860.

THAT this excellent treatise on Qualitative Analysis has already reached a third edition is a sufficient proof of its merits, and furnishes a striking indication of the extent to which practical chemistry is now cultivated in England. This may be regarded as the prototype of the greater number of the smaller essays on the same subject which have of late years issued from the press. It is a treatise complete in itself, and with which it is impossible to dispense in a working laboratory. The descriptions of the chemical processes are clear and precise, and such as may be easily mastered by a student of ordinary industry and capacity.

We observe that, since the first edition, which was noticed in this journal, there have been numerous additions, and the size of the work has been increased by fifty pages; in fact, both author and editor have striven to make it as perfect as the present state of science will admit. Comparative tables of foreign weights and measures might be added with advantage in an appendix.

Of the second part of this work, *Quantitative Analysis*, we are unable to express an opinion, as we have not seen it; but we can strongly recommend the part before us, *Qualitative Analysis*, as a most serviceable and safe guide to the chemical student.

* The italics are our own.

Elements of Chemistry, including the Application of the Sciences to the Arts. By THOMAS GRAHAM, F.R.S., L. & E., &c. 2d edition. Part IV. London: Baillière. 1852.

We are glad to be able to announce the completion of the first volume of this excellent treatise on chemistry. The fourth part is now before us. It contains the chemical history of the *Alkali-genuous metals* and their compounds, with an account of the metallic bases of the *Earths*. The salts of these bases are duly noticed, and the mode of preparing those which are manufactured on a large scale duly illustrated by wood-engravings. We have examined this part, and find that it contains what might have been anticipated from the well-known reputation of the author—a lucid account of the most important improvements and discoveries which have been made in the science since the publication of the first edition. We must also observe that the volume now completed is an admirable specimen of typography, and creditable to printer and publisher for the care with which it has been got up.

Des Kramphaste Asthma der Erwachsenen. Von Dr. J. BERGSON. 8vo. pp. 142. Nordhausen: Bücking. 1850.

On the Spasmodic Asthma of Adults. By Dr. BERGSON.

In the year 1845, the Royal Society of Sciences at Göttingen announced the above subject for the prize which they offered. Dr. Bergson directed his attention to its consideration, and obtained the award for the essay now before us, the contents of which we here briefly enumerate.

The author introduces his investigations with an extensive historical sketch, with true German industry and lore bringing under notice the opinions of every author of importance from the earliest ages of medicine down to the present time. In the next place, Dr. Bergson inquires into the real nature of spasmodic asthma, and concludes that it is a distinct affection, separate from other forms of dyspnoea with which it has been confounded by many modern writers, and that it is an essentially nervous disorder. In order to establish this point, the author draws a parallel between this and other nervous in the several aspects

of ætiology, prognosis, and therapeutics: in this portion of his treatise the author touches upon the essential point of the inquiry, and fully describes the diagnosis of the disease.

The course of the disease is then traced by the author, and its anatomical characters are described. It is shown that the muscular fibres of the bronchi, and the motor influence of the vagus nerve, are in abnormal conditions, that the disease thence consists in a spasm of the muscular apparatus of the lungs.

On the view thus taken by the author, he divides spasmodic asthma, with reference to its causes, into cerebral and spinal, and the latter into centric and eccentric. The work concludes with a very full diagnosis of spasmodic asthma from other diseases of the chest. This is arranged in a tabular form, the characteristic symptoms of the affections in each case being arranged side by side, so as to present their prominent features in obvious juxtaposition.

We can speak highly of this essay, and can recommend it to every reader of German medical literature.

The Brain the sole Centre of the Human Nervous System. By EDWIN LEE, Member of the Principal European Medical and Chirurgial Societies. Pamphlet, 8vo. pp. 14. Edinburgh. 1848.

In this paper the author endeavours to establish the position that the conclusions drawn by Dr. Marshall Hall and others, from their experiments on cold-blooded animals, are applicable only to those classes, and—by quotations from various authors compared with and added to his own observations—to prove that the phenomena of the spinal system, even when manifested separately from the cerebral influence, are owing to the persistence of that influence in the fibres of the cord. In his view the grey matter of the cord and sympathetic ganglia are reservoirs of power, and the brain alone is the nervous centre, controlling and modifying the functions of other parts of the system. Such is an outline of the contents of this pamphlet, to which we must refer our readers for the reasons adduced by the author in support of his views.

A Manual of Qualitative Analysis. By ROBERT GALLOWAY, F.C.S. Small 8vo. pp. 119. London: Churchill. 1850.

MR. GALLOWAY was formerly Chemical Assistant in the Museum of Practical Geology. Although there was no deficiency of works on practical chemistry, he considered that the majority of them were better adapted for the advanced student than for the beginner. With this view he has prepared a compendium of the general rules to be pursued in the qualitative analysis of different substances. Such is the history of the book before us. We have looked over these rules, and find them to be adapted for the purpose intended. They will guide the beginner, and lead him to look upon larger treatises with less fear of mastering their contents. The essay is strictly confined to practical manipulation in the laboratory.

The Physiology of Digestion. By ANDREW COMBE, M.D., &c. Ninth Edition. Edited by JAMES COXE, M.D. 8vo., pp. 191. Edinburgh: MacLachlan. London: Simpkin and Co. 1849.

THE publication of a ninth edition, as well as the sale of more than 16,000 copies of this work within ten years, is sufficient to prove that it is well known to, and, we believe, extensively read, both by the public and the profession. The present edition, by the author's nephew, has been carefully revised, and additions have been made where the present state of science had rendered them necessary.

A Treatise on the Gout; its Nature and Treatment. By H. B. C. HILLIER, M.D. Pamphlet, 8vo. pp. 23. London: Longmans.

DR. HILLIER'S views may be gathered from the following extracts relative to gout:—

"It is hereditary: it does not occur till after puberty: it attacks men oftener than women: it seldom attacks those who live on vegetable diet: it appears to exist in persons of a peculiar diathesis, which diathesis appears to be altered after every fit of the disease: it is seldom fatal: it is assimilated with rheumatism: the treatment which relieves the one does not cure the other; the pain which characterises this disease is peculiar to the gout: it is not met with in every climate." (p. 15).

"I am not inclined to believe that the cause of this disease is in the blood alone, but that it is engendered by and dependent upon unhealthy chyme." (p. 19).

The treatment founded upon these views consists in the use of "the mixed alkalies combined with magnesia and henbane, in frequently repeated doses." (p. 20.)

The subject is treated very fully, and the author displays considerable acquaintance with the views of ancient medical writers.

The Eighteenth Annual Report of the Trustees of the Perkins Institution, and Massachusetts Institution for the Blind. Pamphlet. 8vo. 1850.

THIS Report constitutes a valuable document relative to the management and instruction of the blind. From some experience in the direction of a similar institution, we can speak highly of the remarks and suggestions of Dr. Howe, the writer of the Report. Beyond these considerations, however, the pamphlet before us has deep interest in the subsequent narrative, by Dr. Howe, of the case of Laura Bridgman, whose history has gained a world-wide celebrity from the graphic pens of Washington Irving and Charles Dickens. The Report is no mere record of dry matter-of-fact details, but a stirring and instructive appeal on behalf of the most helpless of our afflicted brethren, which we hope may not be without its answer both on that and on this side of the Atlantic.

The Baths of Rhenish Germany: with Notices of adjacent Towns. By EDWIN LEE. 8vo. pp. 134. London: Churchill. 1850.

THIS work consists of an abridgment of a portion of the author's larger work on "The Baths of Germany." Mr. Lee has been induced to publish this smaller volume, "in accordance with the opinion of the foreign booksellers, for the accommodation of visitors to the Rhine." It will be found useful to those for whom it is intended.

Pestilence; its Source and Suppression. Pamphlet. 8vo. pp. 23. Isle of Man: Quiggin. London: Simpkin and Co. 1850.

THIS medley of scientific words, and extracts from Holy Writ is utterly unintelligible to us.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Nov. 12,

Dr. ADDISON, PRESIDENT, in the Chair.

History of a Successful Case of Ovariotomy; by W. E. DUFFIN, Surgeon. With a Description of the Morbid Anatomy of the Sac; by ROBERT LEE, M.D., F.R.S.

A WOMAN, 38 years of age, having her abdomen enlarged to the size of the eighth month of pregnancy, this size having been attained in 7 or 8 months, her general health appearing to be good, applied to the author for relief by operation. The rapid growth of the tumor, which appeared to be connected with the left ovary, had been accompanied by neuralgic pains in the right thigh, in consequence of pressure on the sciatic nerve of that side. The tumor was very moveable, indicating the absence of adhesions. The patient was very urgent in her desire for the operation, and very confident that it would be successful, and it was consequently performed, on the 27th of August last, by the author, assisted by Messrs. Fergusson, Ure, and Henry Smith, chloroform having been previously administered by Dr. Snow. The incision, at first of only sufficient size to admit the forefinger for exploration, afterwards enlarged to three inches, was made in the linea alba, midway between the umbilicus and the pubes. The absence of adhesions having been ascertained, the sac was punctured by a trocar, and 130 ounces of a viscid, ropy fluid, of a light brown colour, were let out. The collapsed cyst, containing a smaller cyst the size of an orange, was drawn through the incision, and its pedicle secured by ligatures. The tumor was then separated, and the pedicle and ligatures were prevented from receding into the cavity of the abdomen by other ligatures attaching them to the wound. The ligatures came away on the 15th day, and the wound was healed on the 22d day, the abdomen resuming its natural shape and size.

The patient was kept on a light diet, took opium in sufficient doses for six successive nights, and the bowels were opened by enemata. On the 18th day she was able to get about a little. Her recovery has been complete, and she has been enabled to resume the occupation of dressmaker.

Dissection of the Cyst, by Robert Lee,

M.D., F.R.S.—The walls of the cyst are composed of three distinct coats or layers. First, a peritoneal covering; secondly, a middle fibrous coat; and thirdly, a dense membranous sac, in which the fluid was contained. In the divided pedicle are seen the cut ends of three large arteries, and of one large vein, and of the fallopian tube. The peritoneal coat is thin, and loosely attached at the root of the cyst; but beyond this it is thick, opaque, and firmly adherent to the tissues below. The middle coat is thick at the root, and contains numerous branches of arteries, and of nerves with ganglionic enlargements. It becomes thinner as it is expanded over the cyst, is of a dense fibrous structure, and adheres firmly by both its surfaces. The internal membrane is firm and thick, and its inner surface is rough, irregularly puckered, and in some spots of a brown or yellowish colour. It consists of two distinct layers, like the coats of a Graafian vesicle. A smaller cyst is situated near the root of the larger, imbedded in its middle coat, projecting into its cavity, and invested by its lining membrane, which it has pushed before it. The lining membrane of this smaller cyst also consists of two distinct layers, like that of the large cyst.

A group of small multilocular cysts is contained in the middle fibrous coat of the great cyst, and between the outer surface of the smaller cyst and the peritoneum. They have the same structure, contain a similar fluid, and bear the same relation to one another, as the two cysts above described. The author remarks, that "the walls of this ovarian cyst contain all the elementary structures which enter into the composition of the human ovary in the healthy condition—peritoneum, steoma, and Graafian vesicles, with blood-vessels and ganglionic nerves. Whether all multilocular cysts are formed in the same manner, future observation must determine."

An Analysis of 108 Cases of Ovariotomy which have occurred in Great Britain.

By ROBERT LEE, M.D., F.R.S., Fellow of the Royal College of Physicians, Physician to the British Lying-in Hospital, Physician Accoucheur to the St. Marylebone Infirmary, and Lecturer on Midwifery, and the Diseases of Women and Children, at St. George's Hospital.

The author commences with the history of a case of ovarian dropsy successfully removed by a surgical operation, and reported in the Edinburgh Medical and Surgical Journal, for 1822, by Dr. Nathan Smith, Professor of Physic and Surgery in Yale College, Connecticut. He then gives an account of an operation performed by Mr. John Lizars, of Edinburgh, in 1823,

when an ovarian disease was found after the abdomen had been opened; and of three other operations by the same surgeon, when the diagnosis was more accurate, in 1826 and 1826; and of two operations by Dr. Granville, in 1826 and 1827. He then refers to an operation performed, in 1833, by Mr. Jeaffreson; and to three operations by Mr. King, in 1834 and 1834.

During the last 37 years the operation has been attempted or performed more than 130 times in Great Britain, of 106 cases of which authentic reports have been received. In 37 cases either no ovarian cyst or tumor to remove existed, or there were present ovarian cysts and tumors, the removal of which was found to be impracticable, and the operation was abandoned. Of these 37 cases 14 died. The analysis given of 106 cases of ovariectomy shows that in 37, or about one-third of the whole number, it was impossible to determine *previously* whether ovarian disease actually existed, or, when it did exist, whether its removal was practicable. Of the 71 cases in which ovarian cysts and tumors were removed, 24 proved fatal, in 14 of which the operation could not be completed.

In the tabular analysis of the 106 cases appended to the paper, it appears that 45 cases are reported by Dr. Clay, and 11 by Mr. Lane; and to both of these gentlemen the author expresses his thanks for the manner in which they have communicated to him the entire results of their experience of the operation.

PATHOLOGICAL SOCIETY OF LONDON.

Nov. 5, 1850.

DR. LATEAM, PRESIDENT.

MR. COULSON exhibited a heart taken from a man aged 50, who had suffered for many years from chronic bronchitis and dyspnoea. The dyspnoea became very urgent for 30 hours before he died. On examination there was general serous infiltration into the tissues, not amounting to anasarca, considerable effusion into the right pleural cavity, and the left pleura pulmonalis was intensely adherent. The pericardium contained 3 oz. of sanguineo-serous fluid; the liver was congested, and the kidneys large and mottled. The weight of the heart was 28 oz. avoirdupois, and the aortic valves were very extensively diseased, one of them being partly separated from its attachments, so as to allow a portion of the curtain to be retroverted. The other valves

were thickened, and studded with vegetations, and a large part of the free fold of the mitral valve was covered by a thick and irregular layer of recent lymph. The left ventricle was greatly hypertrophied and dilated.

DR. PRACOCK remarked, that the heart exhibited afforded a very characteristic example of obstructive and regurgitant aortic valvular disease. The sigmoid valves were all much thickened and indurated, and must thus, for a long time, have formed an obstruction to the flow of blood from the ventricle into the aorta. When the attachments of the right valve, which was the most extensively diseased, gave way, and allowed its curtain to be retroverted, an aperture had been created, by which, during the diastole of the heart, the blood must have freely regurgitated from the aorta into the ventricle. To the operation of these two causes the large amount of hypertrophy and dilatation of the left ventricle was to be ascribed. The patch of lymph on the free fold of the mitral valve lay directly in the course of the regurgitant current, and was probably a simple deposition from the blood. The specimen further afforded an example of what had been termed "aneurism of the valves." In the curtain of the posterior sigmoid valve there was found a small sac, which opened into the corresponding sinus of Valsalva; and, again, in the free fold of the mitral valve, there was a similar, though smaller sac, which communicated with the ventricle.

MR. TOYNER exhibited a specimen of *Neuroma of the Auditory Nerve,*

which was removed from a man aged 60. The only symptom indicative of its presence during life was a diminution of the power of hearing. The disease consists of a white tumor, about the size of a small bean, which occupies the internal auditory meatus, and projects about a line beyond its posterior border. The shape of the tumor is conical, the small extremity being situated at the anterior part of the meatus: its texture is firm posteriorly; and, upon being cut into, presents but little cellular tissue: anteriorly it is softer. The tumor is attached to a portion of the auditory nerve supplying the vestibule, the fibres of which enter its middle part; and they emerge at its anterior extremity, entering the vestibule with filaments from the healthy portion of the nerve. The nerve supplying the cochlea is unaffected by the tumor; the portio dura lies on its upper surface. Upon examination with the microscope, the tumor, at its anterior part, was found to be composed of distinct nerve tubes, which assumed the varicose form

upon the slightest pressure, and of others about the same size, but more opaque, presenting in their walls distinct nucleated cells, and having the appearance of nerve tubes in the process of development, as delineated by Schwann; these two kinds of nerve-tubes were about equally distributed through the anterior part of the tumor, and between them rounded cells were interspersed. The posterior part of the tumor was observed to consist of fibres running parallel to each other: they are not so large as the tubes in the anterior part; some of them present distinct nucleated cells.

Mr. CANTON exhibited a specimen of
Ossification of the Pericardium.

Master E. B—, *et. 11 years*, in Feb. 1844, suffered from a severe attack of acute rheumatism. A fortnight after its commencement pericarditis supervened, and was treated by leeching, blisters, mercury to ptyalism, colchicum, &c. The following May the medical attendance ceased. Auscultation gave evidence of fibrinous deposit on the pericardium, and there was turbulent cardiac action, with dyspnea. In all other respects he enjoyed tolerable health until November 1845, when pain in the region of the heart required antiphlogistic treatment and blistering for a short time. In April 1846 he became the subject of a severe attack of hamoptysis, which, being subdued, was followed by ascites: this latter was with difficulty removed by diuretics in June. In June 1847 ascites reappeared, but was again removed by the same plan of treatment. In September 1848 he was again dropsical, and continued so for several weeks. The ascites recurred at the close of 1849, accompanied by a severe attack of hamoptysis, which for several days threatened his existence, but was ultimately stayed by gallic acid. His sufferings during the last three years had been very severe, and from this date (Nov. 1849) were still augmented, and obliged him to pass several successive nights supported in a chair. There was great abdominal distension, attended at times with severe pain in the epigastric region; oedema of the lower extremities and of the scrotum. A more formidable attack of hamoptysis again took place in July, and lasted ten days. It now became manifest that the long-continued sufferings of the patient were drawing to a close: the dyspnea became painfully urgent; the ascites was no longer amenable to treatment; and the violent action of the heart prevented him sleeping. Repeated auscultation led to the conclusion that extensive adhesion of the pericardium was present, with hypertrophy of the heart: some disease of the valves

was suspected. During the whole of his illness the pulse maintained a strong, full, and rapid beat, and lessened the suspicion of valvular disease. The carotid and temporal arteries pulsated violently: a dry cough repeatedly harassed him, especially towards the close of his existence.

Notwithstanding his disease and suffering, he grew in stature, and was at the time of his death six feet in height. He died rather suddenly on the 11th September.

Examination.—The anterior mediastinum was filled with old tenacious lymph; the pericardium firmly united to the heart; and in the adhesions, bony matter, forming a ring, was deposited, encircling the organ between the auricles and ventricles; the ring, in the chief part of its circumference, was an inch in breadth; the heart much enlarged; valves on the right side healthy, on the left somewhat thickened.

Abdomen.—The whole surface of the peritoneum overlaid with firmly adherent lymph, obscuring and agglutinating the viscera. Liver enlarged, and kidneys healthy; ascites to a small extent, with a little recent fibrin on the small intestines.

Dr. O. WARD exhibited a

Portion of a Gall-Bladder discharged externally.

Miss T., *et. 48*, has had very severe cough and purulent expectoration, attended with signs of a cavity in the left lung, and other symptoms of phthisis, for more than 20 years. About eight years ago she had an attack of vomiting and diarrhoea, with faintness, when a tumor was discovered on the right side of the abdomen, but apparently unconnected with the liver. As it increased in size the tumor passed more into the centre of the abdomen, leaving a marked sulcus between it and the liver. For a twelvemonth it had descended towards the right iliac region, when it pointed and burst, in April last, a little lower than the edge of the transversalis muscle, and midway between the spine of the ilium and the pubes. The discharge at first was very offensive pus, followed in a few days by numbers of hydatids of various sizes, from a pea to a turkey's egg, and some very minute ones in clusters, with pedicles like a bunch of grapes, and striated externally. In about five weeks the hydatids were all expelled, and the pus became healthy and less offensive. The opening continued to discharge till August 11th, when she had another bilious attack, and the discharge ceased; the abdomen became tense and tender over the right side, with occasional rigors. On the 15th the orifice reopened, discharging pure bile, which continued to flow, to the amount of about a pint a day, till the 24th, when a

alough came away, which, on examination, proved to be a portion of the gall-bladder, having small calcareous plates imbedded in it, similar to some that had passed occasionally from the wound. The bile has continued to pass, in greater or less quantity, almost uninterruptedly to the present time, when there is about a drachm passed in 24 hours. The patient's health has varied considerably, as she is sometimes able to go about the house, and, again, has been reduced so low as not to be able to rise up in bed without support.

Dr. GARROD exhibited, for Mr. DENNY, a
Piece of Bone and Teeth,

which were dissected from between two layers of membrane forming the walls of an ovarian cyst, taken from a girl after death.

Elisa F—, aged 22 years, single, was admitted at the Stoke Newington Dispensary, under Dr. Duesbury, August 9th, 1860, with dropsical swelling, distending so uniformly the abdominal parietes that it was difficult to diagnose whether it was ovarian disease or ascites. She complained of weakness, and inconvenience from the weight and size of the body. She stated that she had been ailing for three years and upwards, during which period she had suffered much from pain in the left side of the abdomen, but had not perceived her body enlarging more than two years; that it had increased much more rapidly of late. She attended at the Dispensary, and slightly improved in health under tonics and diuretics until a fortnight previous to her death, when she was attacked with peritonitis, and died on the 7th of October.

Mr. Price attended her, for a considerable period, for what he considered to be an ovarian tumor; and four months previous to her being admitted a patient at the Dispensary (in consequence of the lady with whom she lived as servant having suspicions of her being pregnant) he sent her to Dr. Lee, who pronounced the uterus to be impregnated, and confirmed the previous diagnosis as to the existence of an ovarian tumor.

On opening the abdomen, the left ovary was found to have been converted into a cyst, occupying the greater portion of that cavity, the viscera of which it was compressing in every direction. A few recently deposited threads of lymph extended from its anterior surface to the peritoneum lining the abdominal parietes; otherwise it was perfectly detached except by its peduncle, which was not longer than the little finger, and consisted merely of the obliterated fallopian tube, enlarged vessels, and peritoneum. The cyst, together with the uterus and its appendages,

were removed; and, on opening the cyst, from three to four gallons of a cream-coloured fluid escaped, suspended in which were numerous flakes of fatty matter: it also contained a large conglomerate mass, as large as the fetal head at six months, consisting of hair (4 to 5 inches long) and this fatty substance matted together, and many smaller pieces of the same substance.

The cyst was divided by transverse bands, and also into pouches, or smaller cysts opening into the common cavity. Adhering to the walls in places were considerable quantities of the fatty matter and attached hair, similar to that in the mass; and between two layers of the membrane forming the wall of the cyst on the left side was the specimen reduced. The teeth are in every respect perfect, with their fangs inserted into processes of the bone resembling the alveolar processes of the jaw.

The right ovary was rather larger than natural, congested, and contained several smaller cysts the size of a pea, filled with fatty matter.

The uterus presented the appearance in all respects of that of a virgin, and healthy, with the exception of slight congestion, which might be merely post-mortem.

Dr. Baillie mentions similar fatty matter, hair, bone, and the rudiments of teeth (but without fangs), having been found in ovarian tumors, and under circumstances leaving little doubt that they had been formed independently of impregnation, one case of which occurred in his own practice. Also a case published in the Philosophical Transactions, where this change in the ovary was found in a child whose age did not exceed 12 or 13 years, with the hymen perfect, the uterus not increased in bulk as is usual at puberty, together with the other signs of puberty wanting.

From the fact of the uterus being totally devoid of all those changes that follow impregnation, whether the fetus be developed within its cavity, or as an extra-uterine foetation within the ovary or fallopian tube, from the respectability of the girl's parents, together with the good character she herself had borne, and her anxious desire that her body should be opened for the satisfaction of her friends, in consequence of the suspicion that her appearance had excited, Mr. Denny was led to believe that in this case there had been no impregnation.

The consideration of this case suggests whether an ovum which the stimulus of the catamenial period caused to burst from the Graafian vesicle, and which was prevented from passing off with the menstrual discharge by the impermeability of the

fallopian tube, might not become adherent to the lining membrane of the ovary or fallopian tube, and thus obtain nourishment, setting in action a power, which may be inherent in it of developing the structures of the body, but in an incoherent manner, without the power to regulate the formation, or to produce a circulating system or nervous centre, necessary to the perfect development and independent life of the fetus. The latter power may emanate from the male, exerting an influence in some way analogous to the electric influence excited in crystallization, of attracting and arranging the particles, so as to give a definite form, and thus to characterize the individuality of the salt.

The statistical information furnished by the record of these cases, especially with evidences of existing virginity, may, by affording data for physiologists, enable them, at some future period, to throw light upon the functions of the ovary, and upon the elements supplied towards the formation, and the power exercised over the development of the fetus by the sexes individually, and may also prove of practical importance in removing the odium which a supposition of the necessity of impregnation might cast upon the fair fame of the innocent.

DR. J. R. BENNETT, PRESIDENT.

Mortality in Hospitals.

DR. HARE, of University College, made some observations on certain points of Dr. Webster's statement last week, which, without some explanation, might tend to mislead, and to give rise to very erroneous inferences. The subject alluded to was the statement with reference to the number of beds, and the relative mortality in the different metropolitan hospitals. Thus it was stated that the beds in University College Hospital amounted only to 106; while the fact was, that the beds were now, and had long been, 122. On the other hand, the number of beds in some of the other hospitals, as stated in Dr. Webster's paper, was overrated. Dr. Hare then proceeded to show that the number of beds in an hospital was no certain criterion of the number of beds occupied by patients, and based his arguments upon a paper published by the Registrar-general on the 29th of June last. An account was there given of the number of patients in the different public institutions on March 31, 1850; and this was the most recent authentic account

which had been published. It appeared, then, that on that day the Royal Free Hospital, which, in Dr. Webster's Report, was put down as having 140 beds, had only 52 inmates; that King's College Hospital, which was put down for 120 beds, had only 96 inmates; while University College Hospital, which, according to the Report, only contains 106 beds, had actually 118 inmates. A short time since, every bed in the hospital was full (122); and on inquiry that day (Nov. 9), Dr. Hare found that the number of in-patients was 112. He then pointed out that, supposing the table had been quite correct as to the number of beds, or even the number of beds occupied—nay, even the number of admissions—in each hospital, still no conclusions or inferences whatever should be drawn from the relative amount of mortality they present, seeing that that is constantly fluctuating, and that fortuitous circumstances so much influence the result. If, however, the number of deaths be compared with the average number of patients in the hospitals (which is a somewhat more accurate method than that of taking the number of beds, even if these be correctly ascertained), it would appear, according to the Registrar-general's document, already referred to, that instead of having the largest percentage of mortality, as stated in Dr. Webster's paper, the mortality in University College Hospital was actually less than the average; for while, in the document alluded to, the average annual mortality of all the London general hospitals was 82 per cent., that of University College Hospital was only 79 per cent. Dr. Hare entered into some further details illustrative of the subject, and pointed out how the much larger relative mortality, mentioned by the Registrar-general as occurring in the London Hospital, and in King's College Hospital (116 per cent. in the former, and 158 per cent. in the latter), might be accounted for without supposing that there occurred in these institutions any larger number of deaths, relatively to the severity of the cases admitted, than in any other hospital of London.

Dr. SIMSON made some remarks with the view of showing that the actual number of patients in an hospital, and the actual number of deaths, did not convey in all cases a fair estimate of the mortality of the institution, when compared with others. Thus the previous condition of the patients, the situation of the hospital, the nature of the maladies under which the inmates laboured, and other elements of inquiry, were necessary before a right conclusion could be arrived at.

Dr. WEBSTER, after stating that he had availed himself of every possible means of

making his inquiries accurate, said that he should be most happy to have any of his statistics corrected. With reference to the number of beds for patients in University College Hospital, he could find no published statement, and he believed there was none. He had, however, the written authority of a medical officer of that institution for stating that "there are 106 beds laid out at University College Hospital," and Dr. Hare now acknowledged the mortality was correctly reported. Respecting the other subjects alluded to by previous speakers, as they formed no part of his (Dr. Webster's) paper, or of the abstract recently published, it seemed unnecessary to advert thereon, or to the quotations just read from the Registrar-general's Report bearing upon the mortality in hospitals, although such remarks were of the highest value, and the opinions now expressed deserved respect. The discussion that evening, however, clearly indicated the advantage of having regular statements from all the metropolitan hospitals, and how useful they would be to the profession, as he (Dr. Webster) had suggested in his communication.

SURGICAL SOCIETY OF PARIS.

Serious and multiple Injuries occurring to an Old Man—Amputation of the Arm—Ligature of the Axillary Artery—Cure.

A MAN, aged 70 years, fell from a heavily laden vehicle, one of the wheels of which passing over him, produced fractures of both thigh-bones, comminuted fracture of the radius on the right side, and compound fracture of the humerus. Amputation was considered requisite. M. CHASSAIGNAC performed it at the level of the insertion of the deltoid. An external flap was formed, so that the extent of injury to the bone could be ascertained. Secondary hæmorrhage occurred repeatedly, and rendered ligature of the axillary artery indispensable: this was effected beneath the clavicle.

With reference to a discussion which had taken place in the Society on the question whether the ligature, in becoming separated from an artery, carried with it a portion of its structure, M. CHASSAIGNAC stated that he had directed his observation to this point in the present instance. On the fifteenth day the ligature came away, carrying with it the debris of a portion of artery, equal in length to the width of the ligature, presenting the calibre of the artery and the two cup-like depressions on each

side of the constriction. This fact, M. CHASSAIGNAC observed, is exceptional, as ordinarily, when a portion of the vessel comes off with the ligature, it is extremely small, and consists solely of the portion compressed by the ligature. In the present instance the ligature had been double.

M. LENOX considered the result here stated as unfavourable, and attended with risk of hæmorrhage. He entertained no doubt but that the portion of artery could always be found with the ligature if properly sought for.

M. HUGUET had observed, that with a single ligature, the internal and middle coat having sloughed away, and the external coat having divided, no remains of the vessel comes away with a ligature.

MM. MAISONNEUVE and LARREY concurred in the last opinion.

M. CHASSAIGNAC replied that he had merely stated this fact as having occurred to him, irrespective of any theoretical views; it was an exceptional case; he had never, in other cases of ligature of large vessels, found any trace of their structure; and he suggested it as probable that the age of the patient might have contributed to this unusual result.

A report was read on M. Blot's Essay on the Albuminuria in Pregnant Women. (We have elsewhere given an abstract of this essay.)

Painful Tumor of the Face.

M. CHASSAIGNAC presented a patient, a man 30 years of age, of a good constitution, in whom a tumor had been developed on the inferior maxilla, in the site of, and consequent upon the extraction of a molar tooth. It had attained the size of a hen's egg, and was productive of severe lancinating pains. The skin over it was unaltered; to the feel it was elastic, and presented a doubtful sense of fluctuation: it was adherent to the bone, and an explorative puncture had proved it to be solid. M. CHASSAIGNAC regarded this growth as being of a cancerous nature, but hesitated to remove it, as he feared that the bone itself might be diseased.

M. FOREST was disposed to regard the tumor as of a fibrous character, and suggested its removal, with a portion of the bone, to secure against its return.

Medical Trials and Inquests.

COURT OF ASSIZES, DARMSTADT.

March 11th—April 11th, 1850.

Trial of John Stauff for the murder of the Countess of Goerlitz—Alleged spontaneous combustion of the body—Report of the Hessian Medical College on the case.

[We are indebted to an eminent Scotch medical jurist for the abstract of the following remarkable case.]

The abstract of the instructive trial which follows is taken from the two medico-legal periodicals whose titles will be found below.* The mode in which the crime had been gone about, which had nearly defeated the ends of justice, and even baffled suspicion, the number of scientific witnesses employed, and the nature of their investigations, embracing as they do the difficult and hitherto unsettled question of the so termed "spontaneous combustion" of the human body, will we think justify us in giving a pretty full outline of the particulars of this remarkable case, from the documents before us.

From the report of Dr. Graff, of Darmstadt, it appears that the late Countess of Goerlitz, *et. 46*, a person of active, industrious, and somewhat parsimonious habits, and in the enjoyment of good health, was frequently known to retire to her own apartments, and shut herself up there for half a day at a time. On the 13th of June, 1847, between 3 and 4 P.M., on her husband going out to dinner, she had retired to her room to arrange some household matters. Her servants had obtained permission to absent themselves for the evening, leaving only the prisoner Stauff in charge of the house. The Countess's private apartments consisted of an ante-chamber, and a parlour (*Wohnzimmer*) inside of this, into which opened a closet (*Kabinete*), only large enough to contain an ottoman (*divan*), on which she commonly took her siesta. In one corner of the parlour was a Russian stove, and in another her writing-desk (*schreibpult*). On his return in the evening the Count knocked at the door of the anteroom, but received no answer, when he went out again. This

was about seven o'clock by 9 A.M. became back. During his second absence a bright light, which speedily disappeared, had been noticed at the closet window, which looked to the south, and also a thick smoke from a chimney which corresponded with the stove in the parlour. At 9 P.M. the servants, who had returned, were sent in search of their mistress, but not obtaining entrance, workmen were sent for to break up the doors of the outer rooms, which were locked. The keys were not afterwards to be found. The smoke which issued from the rooms prevented them from being entered till one of the windows was forced. On this being done flames burst out simultaneously from the hangings, the writing-desk, and the floor underneath it. The dead body of the countess was found, a foot from the writing-desk, with the feet towards the middle of the room, and the head towards the window. There was no appearance of fire about it, or at the part of the inlaid wooden floor on which it rested. On its removal a few embers (*cinder*, = 15·12 imperial gallons) of water sufficed to extinguish the fire. On this being effected, a rush of smoke was noticed to issue from the open door of the closet, which was found to proceed from the ottoman being on fire. No other object in this apartment was touched, and in front of the ottoman lay one of the Countess's slippers uninjured.

When called in officially on the following morning (14th of June), Dr. Graff found the whole of the Countess's private apartments in the state of disorder usual after the extinction of a fire. The writing-desk had been mostly consumed, and the papers it had contained, partly burned, lay scattered about the room. A mirror on the parlour wall, 16 feet (15 f, 5·84 inch. Eng.) from the writing-desk, was cracked, and two stearine candles which had stood on a chiffonier, 9 feet (9 f, 3·23 inch. Eng.) from it were melted. The ottoman in the closet was displaced, and nearly in its centre was an almost oval hole, caused by the combustion of the hair mattress and stuffing.

On proceeding to view the body, Dr. Graff observed the remaining slipper on one of the feet, and uninjured. The dress on the upper part of the body was almost wholly consumed. The head exhibited the form of a nearly shapeless black mass, in which the mouth was imperfectly distinguishable, with the charred tongue protruding from it. The body lay on its left side, the head and chest retracted, the neck everywhere blackened and charred, as were the skin and muscles on the fore and upper parts of the chest, the former being thus affected to within an inch of the pit of the

* Henke's Zeitschrift für die Staatsarzneikunde, 2 V. H. 1850. Bd. 40. Ergänzungsheft. Bd. 3 V. H. 1850. Annales d'hygiène publique et de Médecine légale, 37 and 38 No. Juillet, Octobre, 1850.

stomach. The marks of the action of fire did not extend quite so far along the back part of the trunk. The joints of both upper extremities were flexed; and their surfaces charred, except at the hands. The left shoulder and the right elbow-joints were laid open. From the former of these the blackened humerus, and from the latter the heads of the radius and ulna, protruded. The skin in the vicinity of the left knee was slightly acted on. The body exhaled an empyreumatic odour. The further examination of it was objected to.

Considering (1) that the deceased had been in full bodily vigour; (2) that she had been seen by her servants the evening before in good health; (3) that she had not gone to bed, but must have been occupied at her writing-desk; (4) that in case of the fire having been accidental, she might have escaped from it, or at least have called for assistance, of which there was no indication, though she was close to a window; and (5), that as the traces of the fire and the carbonization of the body were chiefly about the head, and that the open mouth and protruded tongue were indicative of suffocation and impending asphyxia, Dr. Graff reports it as highly probable that this had been one of the rare instances of what is termed *spontaneous combustion*; a supposition, in his opinion, which alone could explain the circumstances that the deceased had been unable to call for assistance, or to save herself, as she must have done had the light on the writing-desk caught her hair or head-dress.

This opinion Dr. Graff so far qualified next day, by farther reporting that his conclusion in regard to the high probability of death by spontaneous combustion, in this instance, was an hypothesis only admissible in the absence of indications of violence on the body, the abstract possibility of which he was not prepared to deny, or that the burns, particularly those about the head and neck, might not have been resorted to to mask such violence; in which case the protrusion of the tongue, and the open mouth, would give support to the presumption of strangulation.

Report of Dr. Stegmayer, 27th December, 1847.—Dr. Stegmayer, who seems to have been the fatally medical attendant, could not say whether or not there had been anything in the mode of life, the constitution, or the usual state of health of the Countess, which would give support to the hypothesis of spontaneous combustion in her case. He had not himself observed her using spirituous liquors, nor witnessed anything which could lead him to conclude that she was addicted to the abuse of them. There was nothing in the state of the dead body, as seen by him, or as spoken

to by the servants, which could indicate that it had been exposed to the action of fire during life.

Report of Dr. von Siebold, 12th April, 1848.—In this document Dr. von Siebold seeks to corroborate the opinion previously adduced by him in his *visu vœce* examination, to the effect that the Countess had perished by spontaneous combustion. In proof of the occasional occurrence of death in this way, he points to the instances adduced by Kopp, Friedreich, Henke, and Devergie. He enumerates the leading features of the cases collected by Devergie in the article on "Spontaneous Human Combustion," in the *Diet. de Méd. et de Chir. Pract.*

These may be left out here, as they will be given below in our notice of Dr. Graff's second report. We may also here omit that portion of his summary of the facts elicited regarding the death of the Countess already given from Dr. Graff's first report, confining ourselves to a few points omitted in this last document.

He viewed the body (along with Dr. Stegmayer) at 11 P.M. on the night of the fire. The surface of the head and neck had a shining fatty appearance, as if covered with a coat of varnish. There were no marks of fire on the clothes anywhere beyond the margins of the burns on the body. On the 26th of November, 1847, it was intimated by the Count that an inquest would be held respecting the fate of the deceased. Next day the cook detected a quantity of greenish matter (*verdigris*) in a sauce intended for the Count. About the same time suspicion was awakened against Stauff, from the discovery of some jewels, which had belonged to the Countess, in the possession of one of his relatives at a distance. A few days after the fire several boxes full of charred matches were found below a small Russian stove in Stauff's room. The bell-pull in the Countess's room was torn away, and lay on the floor at the spot where it had been attached. When the body was found one of the knees was exposed, the lower part of the chemise and the other clothes being turned up. The writing-desk retained its shape; the top and sides of it had only partially suffered: the folding-board (*klappe*) and the drawers, from top to bottom, were entirely consumed, as was the floor beneath and in front of the writing-desk, over a space of a foot and a half. The mirror, and an oil-painting above a sofa in the parlour, were obscured by a coating of soft deep reddish matter, containing black points visible in it, with or without the aid of a lens. The feet of a chair placed near the writing-desk were slightly charred.

From the facts of the case Dr. V. Siebold considered that the burning of the Countess's body could not have been the consequence of accident. The combustion of the desk and the portion of the floor could not have done it; the corpse was found out of the reach of these, and on a part of the floor to which the fire had not extended. The doors and windows were closed, and no flames were observed till the room was forced open; so that the desk and floor were rather charred than burned. The disproportion, besides, between the extent of the burns on the body and the quantity of the combustibles consumed, was too great to allow him to admit that they had been caused by the burning of the furniture. He considered it equally impossible that the burning of the body had been the result of design, and the employment of additional combustible matter. After explaining away the facts which favour the supposition of design, he contends that no murderer could have chosen a mode of concealing his crime so difficult and complicated a kind, which demanded time for its execution, endangered his discovery while putting it in force, required the collection of abundant materials, was likely to leave its traces behind it, and which, in short, none but a madman in the pursuit of some fixed idea was capable of carrying successfully into effect.

He further thinks that the portion of the body burned could not have been introduced at once or separately into the stove; that the coating on the mirror showed that the combustion had taken place in the room; and that the state of the apartment indicated that no particular arrangements had been made for this purpose.

He contends, in addition, that spontaneous combustion alone can satisfactorily explain the circumstances of the case; such as the limitation of the burning to the upper part of the body and of the dress, while it had extended to the upper extremities; the coating on the mirror and the oil painting, and the appearance of the burned parts. Supposing that the combustion had begun at the head, and that the eyes had only been partially involved in it, the Countess might at the moment have been in a state to run to the bell-pull; and, in her agony, to pull it till it gave way. The flame seen from a house opposite the closet window at 8 o'clock showed that she had been lying on the ottoman when the head had taken fire, which accounted for the hole burned on it, and for the disfigurement of the mirror and the oil painting, as well as the finding of the slipper in this apartment. He conjectures that the Countess was in the act of run-

ning to the window to call for assistance when she had fallen before the writing-desk and set it on fire.

Report of H. Merck, 16th April, 1848.
—H. Merck carefully examined the brownish coating on the fragments of the mirror. On washing these with distilled water the liquid was brownish and clouded; with potash it gave out ammoniacal fumes: it was feebly acid: distillation, and the addition of concentrated sulphuric acid, showed that it contained acetic acid. The residuum was soluble in alcohol, and the alcoholic solution had a burned and fatty taste. Hence he concludes:—1. That the coating on the mirror had been produced by the slow and imperfect combustion (carbonisation) of organic matters. 2. That it contained ammonia and acetic acid. 3. That the substances from which it had been derived were of a vegetable and animal nature, but not necessarily derived from the combustion of the body of the Countess, since woollen stuffs, feathers, &c., might equally have yielded an ammoniacal product.

Reference to the Medical College of the Grand Duchy of Hesse, 21st July, 1848.*

—On the 23d of June, 1848, the following queries were forwarded to the members of this College for their decision—viz.:

1. Whether, and in how far, it could with certainty be determined either that the death of the Countess had been the result of spontaneous combustion, or that this mode of death was in any case admissible? And in case of a negative answer to both these questions:—

2. Whether, and in how far, grounds of probability existed in this case for or against the likelihood of this mode of death?

3. Whether, and in how far, the employment of the sauce drugged with verdigris, or a portion of it, would have endangered the life or health of the person partaking of it?

It was further intimated to them that, should the disinterment of the body be deemed by them necessary or desirable, in order to the elucidation of the first and second questions, leave should be asked for that purpose.

In reply, the Medical College refer to the annexed document by one of their colleagues, to whose conclusions they give their formal assent.

Report (2d) of Dr. Graff, 14th July, 1848.—After a few preliminary remarks, and a recapitulation of the principal facts already detailed regarding the death of the Countess, and the appearances which her

* The members of the College were Drs. Büchner, Hohenchild, Leidhecker, V. Siebold, Rieger, Graff, and H. Merck.

body presented at the time, Dr. Graff proceeds to compare these last with the results deduced from an analysis of the cases of spontaneous combustion recorded by authors, and especially with those collected in the "Encyclopädisches Wörterbuch der Medicinischen Wissenschaften," amounting in all to about forty cases. In these:—1. The proportion of females to males was as 4 to 1. 2. The parties were mostly of very advanced age, chiefly from 50 to 80 years, namely 59. 3. Their habits were most frequently sedentary and inactive. 4. They were in almost every instance stout and very fat. 5. Almost all had been for years addicted to the excessive use of spirituous liquors. 6. The combustion almost always immediately followed such excesses. 7. It always happened in the night-time, and in winter. 8. Calls for assistance were never heard from the parties. 9. In the majority of the cases, though not in all, there was some burning body in their vicinity. 10. The combustion was excessively rapid, occupying mostly but a few minutes, sometimes only a few seconds. 11. It was attended with flame, and hardly admitted of being extinguished by water. 12. Even very inflammable objects in the person's vicinity often escaped injury from it. 13 and 14. In every instance the combustion involved part of the trunk of the body; and, with few exceptions, this part was always converted into carbon (kohle) and ashes. 15. In the majority of the cases, portions of the head and limbs escaped the action of the fire. 16. The extremities were also severed at the joints, and were covered with vesications. 17. The combustion had always a fatal termination. 18. The charcoal (kohle) which was left mostly retained the form of the part burned, was very porous, and fell into powder on the slightest touch. 19. The ashes were almost constantly intermingled with a yellowish, oily, glutinous liquid, which also covered the floor, and gave out a penetrating empyreumatic odour. 20. The whole chamber was filled with a thick smoke, and the walls and furniture were invested with a dark soot.

Applying the criteria of death from spontaneous combustion thus obtained to the case of the Countess of Goerlitz, Dr. Graff finds that, excepting in the particulars noted above in §§ 1, 8, 19, and 20, the two present no points of agreement; that these points of resemblance besides refer only to generalities, some of which—such as those in §§ 19 and 20—prove nothing, and could all have been caused by the burning of the body under ordinary circumstances; that one other of the two remaining circumstances—that in § 8—

does not admit of satisfactory determination one way or another; and that, in this, particularly if we take into view the proposition in § 9, we have an absolute negative put upon the possibility of spontaneous combustion, in the failure of its most essential conditions, as well as, not only the highest probability, but likewise the absolute certainty that, in this instance, death had not happened from this cause.

Dr. Graff conceives Dr. V. Siebold's hypothesis, as to the train of circumstances attending the Countess's death, to be opposed to the facts stated under §§ 19, 14, and 15. The probabilities, he contends, were all against her having been able to ring for assistance, or to call from her parlour window. He cannot see how his suggestion that she might have rested her hand on the top of her writing-desk, could have set it on fire; or, if so, why the floor was not also kindled at the spot on which her body had fallen (vide § 11). He relates an instance, known to himself, in which the head of a corpse was reduced to a shapeless charred mass, from the accidental combustion of some wood-shavings, and the subsequent spread of the flames to the top of a table above them, on which the body rested, as a proof of the extent of injury which a dead body may suffer from the burning of a limited supply of combustible matter. He states that, although, when first called to view the Countess's body, he had hesitated between spontaneous combustion and murder, he cannot now admit the possibility of the former mode of death in her case, but considers it to have been undoubtedly the work of an assassin. He supposes that an inspection at the time would have shown that there had been not only strangulation in the present instance, but also fracture of the skull; and that even yet, provided the cranial bones had not been completely consumed, the verification of the previous existence of fractures or fissures was not impossible. On these grounds the disinterment of the body is advised.

In reply to the 3d question, Gr. Graff states that the sauce was found to contain 15½ grains of verdigris, a dose of from one to two grains of which was capable of producing dangerous symptoms, and four grains might cause fatal effects.

Disinterment and inspection of the body.

—The body of the Countess was inspected by Drs. Graff, Büchner, and Rieger, and Freniard, surgeon, on the 11th of August, 1848, after upwards of fourteen months' sepulture. It exhaled a moderately strong mouldy putrid odour.

The grave-clothes in contact with the body were moist: they were every where

stained of a more or less deep brown colour: larvae and pupae were found within their folds, and a countless host of small flies, both living and dead, covered most parts of them.

More than two-thirds of the cranial vault were entirely wanting, the greatest deficiency being at its upper and left side. The remaining portions of the skull appeared blackened and charred; but, on removing the blackened masses which adhered to it, the charring and discolouration was found to be but partial, the bones being firm, smooth, and giving out when struck their usual normal sound. A fissure, about half an inch in length, extended downwards from the upper border of the right temporal bone, which was otherwise nearly entire. The remains of the encephalon, in the form of a blackish-brown, half-softened, and adherent mass, of about the 6th or 7th part of its natural bulk, was found at the base of the skull. The lower jaw was in part deficient, and two and a half inches apart from the upper. The cervical vertebrae, the clavicles, and the ribs, were partly blackened, but their texture was unimpaired. The cavity of the chest contained a black fetid pulp, in which only a portion of the heart was distinguishable. The contents of the abdomen were in a putrid state. The right upper extremity had suffered more than the left. The head of the left humerus was charred, and part of it gone. The bones of the forearm were fractured, and portions of their surfaces charred, but their texture was otherwise unaltered, and they gave out their normal sound when struck. On both arms portions of the soft parts remained as a blackened greasy mass. The integuments of the abdomen and thighs had a leathery feel, and a cheesy-looking appearance. The femoral muscles were pretty fresh.

From the data thus obtained, the examiners concluded:—1. That the flames which had acted on the body of the Countess had been chiefly on the left side of it; and 2. In a direction mainly towards the head. 3. That the injuries it had suffered from the fire could not have been produced by spontaneous combustion. 4. That the unusual separation of the remains of the lower from the upper jaw was in accordance with, and merely corroborative of, the position of the mouth previously noticed. 5. That the putrefactive destruction of the peritoneal viscera, in contrast to the putrefactive softening of the abdominal contents, was connected with the penetration of the conflagration within the chest; and 6. That the fissure in the right temporal bone, though possibly caused by the action of fire, may, with at least equal probability, be attributable to me-

chanical violence directed against the skull from without.

Report of the Hessien Medical College, 16th August, 1848.—The members of this body report that the result of the above inspection had corroborated their former opinion (vide Dr. Graff's Second Report, ante) that *the death of the Countess of Geortitz had not been the result of spontaneous combustion.* After enumerating the leading points revealed by the inspection, and premising that though the two cases are not strictly parallel, they conceive they are fairly entitled to draw a comparison between the condition of the bodies of those who had perished by spontaneous combustion, and that of the body of the Countess on its disinterment.

In their previous Report they had shown—1. That in the instances recorded of death by spontaneous combustion the trunk of the body had always, with few exceptions, been reduced to coals and ashes, leaving only small vestiges of the head and limbs; and also, 2. That the coal which remained behind mostly still retained the form of the parts of the body destroyed, was very porous, and on the slightest disturbance crumbled down into dust. What, they argue, do they meet with in the present instance? 1. Instead of a heap of dust and ashes, a body, with the exception of the head, still retaining the human form. 2. Instead of the crumbling down of the burned and charred soft parts, a black, pulpy, greasy, and putrid mass. 3. Instead of the transmutation of the black burned bones into dust and ash, these still retaining their full firmness of texture, their usual hardness, and normal sound. 4. Instead of mouldering integuments and muscles, a compact, firm, dry, leathery skin, and a muscular tissue but little affected with putrefaction. 5. Instead of the falling of the charred fragments of bone into dust on being disturbed, a hard, firm charcoal, with all the qualities of common bone-charcoal.

The members of the college assent to the opinion of the examiners regarding the fissure in the right temporal bone, considering a decided cause for its production impossible to be fixed on, owing to the mutilated state of the skull.

[To be continued.]

EPIDEMIOLOGICAL SOCIETY.

THE meetings will be held on the first Monday evening in the month, from December to August inclusive. For this purpose the Council of the Royal Medical and Chirurgical Society have kindly granted the use of their house in Berners Street until the new society shall have secured the means of obtaining a permanent habitation.

Correspondence.

REVIEW OF CORFE AND MAITLAND ON MEESMERISM.

SIR,—Allow me to correct a slight error into which the reviewer of Maitland and Corfe on Mesmerism in your last number has been led, by the common nomenclature of the doctors who *preach* and the doctors who *practise*. The author of the "Church in the Catacombs," is Dr. Charles Maitland, M.D., the author whose work on Mesmerism is quoted is Dr. Samuel R. Maitland, D.D., of Lambeth. The latter is well-known as the author of "Eruvin," "The Dark Ages," "Letters on the Voluntary System," and sundry critical, bibliographical, and prophetic works.

Yours obediently,

T. K. CHAMBERS.

HHH Street, Berkeley Square.
Nov. 18, 1850.

LIFE ASSURANCE OFFICES AND MEDICAL REFEREES.

SIR,—One of our Medical Officers kindly referred me to a recent number of the MEDICAL GAZETTE, containing a list of Assurance Offices recognising the principle of compensating the private Medical Referees of Life Proposers, in which the name of this Society is omitted.

I shall, therefore, feel greatly obliged by your supplying the omission as soon as convenient.

Your obedient servant,

J. H. JAMES,
Actuary.

English and Cambrian Assurance Society,
for Fire, Life, Annuities, and Loans,
9, New Bridge Street, Blackfriars.

London, Nov. 15, 1850.

*** Mr. James's object will be answered by the insertion of this note.

ANALYSIS OF THE ASHES OF BLOOD. BY M. G. ROSE.

THE author has analysed the ashes of blood which had been previously washed in water, both hot and cold, in alcohol, and in ether. These ashes were found to contain a larger proportion of iron than those not thus treated, which contain a larger proportion of phosphoric acid. The ashes of the lixiviated blood did not contain a sufficient quantity of this acid to form the tribasic phosphate of lime and magnesia. M. Rose concludes from these results that the iron of the blood does not exist in a state of combination with phosphoric acid.—*Journal de Chimie Médicale*, Octobre 1850. x

Medical Intelligence.

ADDRESS TO THE QUEEN FROM THE PRESIDENT AND FELLOWS OF THE ROYAL COLLEGE OF PHYSICIANS.

THE following Address has been delivered to the Home Secretary for presentation to Her Majesty:—

To the Queen's Most Excellent Majesty.

We, Your Majesty's most loyal and dutiful subjects, the President and Fellows of the Royal College of Physicians in London, desire to approach your Majesty with a fervent expression of our devotion to our Sovereign, and of our unalterable attachment to our constitution in Church and State.

We deem it our duty to offer this expression of our principles and loyalty, in consequence of the aggressive measures of the Roman Pontiff,—measures unprecedented in the darkest ages of Papal dominion,—whereby he has assailed the supremacy of the British Crown, and has virtually denied the very existence of a Church in this country, or of Christian faith in Your Majesty's Protestant subjects.

As members of a liberal and highly educated profession, we feel ourselves especially called upon to protest against the moral and intellectual tyranny too often exercised by the Church of Rome. Too often has she endeavoured to fetter the human mind with the chains of ignorance. And, looking to the recent interference of the Pope with secular education in Ireland, we see plainly what would inevitably ensue in England also, if he should be allowed to re-establish here his spiritual power.

While we value and respect the rights of conscience, and desire that no civil disability should be imposed on account of religious opinions, we yet demand that your Majesty's authority, and the rights of the Church, of which your Majesty is the lawful Head, should be maintained inviolate; nor can we endure that these should be prostrated before the intolerant pretensions of a foreign power, and of a Church that will not accept of toleration, but claims an absolute and universal sway over the minds and consciences of men.

We remember that your Majesty's illustrious ancestors of the House of Brunswick were called to the sovereignty of these realms for the express purpose of defending the Protestant faith; and therefore we consider a blow aimed at the Royal supremacy as directed against the foundation of your Majesty's Throne. Although that foundation is laid too deep in the hearts of the

people to be shaken by any such attack, yet we humbly pray your Majesty to adopt such measures as to your Majesty shall seem best for the purpose of repelling the aggressions of which we indignantly complain, of preventing their repetition, and of vindicating, in the eyes of the world, the rights of the Sovereign and of the people of this Protestant land.

MEDICAL STATISTICS OF THE BOROUGH OF PLYMOUTH FOR THE QUARTER ENDING THE 30TH SEPTEMBER, 1850. BY DR. W. HAMILTON.

The population of the borough continues slowly to recover from the formidable reduction effected in its numbers by cholera during the preceding year. Among the various causes which might be assigned for the slowness with which society repairs the breaches which have been made in its numbers, there is one which it is right to notice more especially, as it is one which must of necessity continue to operate yet for a considerably longer period—namely, the havoc which cholera committed among females at ages between the marriageable standard

and that at which child-bearing usually terminates. From an examination of the materials kindly furnished by our registrars, I find that out of 10,169 females who were living, between the ages of 18 and 50, at the commencement of cholera, no fewer than 167, or 1·64 per cent., were carried off; and of these, as I have already shown, in a paper in the MEDICAL GAZETTE of the 4th inst., page 568, at least 98, or above 59·6 per cent., appear to have died between the third and ninth months of gestation; and, as I remark in the place to which I have referred, “that it is no visionary opinion which rests only on the unsubstantial basis of theoretical calculation, appears to be corroborated by a fact, communicated to me upon what I regard as unquestionable authority, of parturition having actually taken place while the mother was labouring under cholera, and this in more than one instance, although I have been unable to ascertain the precise number.”

The following tables exhibit the quarterly movements of the population, as deduced from the returns kindly furnished by the registrars—

Monthly Births and Deaths in the Borough of Plymouth during the Quarter which ended on the 30th of September, 1850:—

	DISTRICT OF ST. ANDREW.						DISTRICT OF CHARLES.					
	1849.			1850.			1849.			1850.

Thus, while during the corresponding quarter of last year population retrograded, under the malignant influence of cholera,

from 39,571 on the 1st of July, to 38,935 on the last day of September, or at the rate of above one and a half per cent., it has

advanced in the present year from 89,905 on the 1st of July, to 89,419 on the last day of September, or 144, being at the rate of 0.286 per cent. In the quarter immediately preceding the eruption of cholera, the increase was from 89,605 on the 1st of April, to 89,571 on the last day of June, being an increase of 166, or at the centesimal rate of about 0.43 per cent.,—nearly one-third more rapid. Should not a third invasion of cholera—an event by no means improbable—take place, we may anticipate a rapid ascent of population to its former level at a progressively increasing rate. In the meantime, we cannot too strenuously urge upon our municipal authorities the necessity of following the example so beneficially set by Ruster, and employ the interval of repose in providing against the possible recurrence of alarm by carefully removing, as far as their power will admit, those causes of mortality which, if they do not create, most assuredly foster and aggravate cholera: *sanissimi occurrere morbo* is a sage maxim of which we should never lose sight.

The temperature of October has been below that of the preceding year, the mean reading for the month having been only 57.5, against 60.58 last year; and the mean reading of every week but the second was equally below that of its corresponding predecessor. The mean temperature of the second week corresponded with that of the preceding year, having been 58 in both.

The atmospheric pressure, on the contrary, was in excess, both on the entire month and in the individual weeks, with the exception of the fourth, when the mean reading was 0.06 below that of the corresponding week.

The mortality during the month has again exceeded the natural increase by births, chiefly from the prevalence of scarlatina, which has been particularly fatal among the young, and yet continues to rage with unmitigated severity. The comparative movement of the population in the two years will be seen in the following table:—

	St. Andrew.			Charles.			Borough.			Movement in the population of borough.

1850	72	74	2	31	40	9	103	114	11	Decrease	47	11
Diff.	30	53		4	17		34	70		31st Oct.	38,888	39,406

Snow fell on Dartmoor on the 25th, in the neighbourhood of Ashburton.

. It is highly creditable to Dr. Hamilton that he thus keeps a careful record of the medical statistics of the town in which he is residing. His example should be followed in other localities. The increase of deaths from certain diseases, when thus noted, leads to the best results, and tends to prevent that excessive mortality which was formerly witnessed from the unchecked ravages of synotic diseases.

ROYAL COLLEGE OF SURGEONS.

THE following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 15th instant:—Messrs. Charles Neate, Maidenhead, Berkshire; William Sutcliffe, Hedben Bridge, Yorkshire; Thomas Clarke Brady, Lifford, County Donegal; Andrew Bolton, Eb-

chester, Durham; James Cummin Toshach, South Shields, Durham; and Robert Turner Bywater, Leeds. At the same meeting of the Court, Dr. John Barclay, of Haaler Hospital, passed his examination for naval surgeon. This gentleman had previously been admitted a member of the Edinburgh College.

FEVER AT ALEXANDRIA.

INTELLIGENCE from Alexandria of Nov. 8th, announces that there has been much fever prevailing there, attended with unusual mortality. Among the deaths last week were those of Mr. W. B. Le Gros, Private Secretary to the Consul-General, Mr. Murray, Dr. P. O'Connor, and Mr. Finnie, surgeon-dentist.

OBITUARY.

ON the 14th inst., at Dorchester, Francis Jackson, Esq., M.D., aged 43.

ON the 15th inst., at Wokingham, Berks, Mr. James Wheeler, formerly surgeon of that place, aged 84.

Selections from Journals.

ON THE STRUCTURE OF THE FIBRE OF VOLUNTARY MUSCLES, AND OF THE HEART, IN DIFFERENT CLASSES OF ANIMALS.

M. LAMEN, of Paris, and M. Prevost, of Geneva, have separately been engaged in microscopical researches on the structure of muscular fibre, and have arrived independently at the same results, which we subjoin:—

In endeavouring to include in a general consideration all the elements which are combined in the production of voluntary muscles, it will be seen that these muscles pass through four phases, or occasional degrees of development, before their texture is completely adapted to the execution of its functions.

The first degree is that of *metastite*, without muscular fibre. The entire animal envelope is capable of contraction and expansion, and of performing rapid movements of progression and swimming, without the detection, by the most powerful microscopes, of fibres, granules, striæ, or cylinders—elements which are early met with in muscular fibre. These movements are analogous to those which are observed under other circumstances in animal and vegetable bodies—movements which are independent of animal life. Such are the vibratile motions of the cilium on the surface of many embryos; those of the spermatic bodies, and of the sporules of algae, of polyps, &c.

In the second degree of development the essential element of muscle, the muscular cylinder, is not met with; but, of its principal parts, the fibre exists. This is found embedded in a transparent intermediate substance, but not arranged in independent bundles. In the animal forms in which this degree is met with the fibres are arranged in superimposed planes, crossing at right angles, composing circular or radiating laminae around the orifices of the body by which the alternate opening and closing of the cavity is effected—the first trace of sphincters. These fibrous laminae are met with in polyps, scalephæ, some molluscs, and annelids. The movements effected by these differ from the preceding in the fact that their direction is more determinate and in accordance with that of the muscular laminae.

The third degree of development is that in which the fibres become aggregated into cylinders or fasciculi, which constitute true independent muscles. This degree is found in the same animals at the same time with the two preceding degrees. This

first sketch of the muscular cylinder offers several varieties in aspect. In some instances the grouping of fibres is but faintly traced, in others it is very distinct. The fasciculi are generally imbedded in a transparent medium of union, which forms the representative of the nuclear tissue of higher animals. It is important also to observe that the muscular fibre offers several varieties in the mode of distribution of the molecular granules in the interior of the cylinders, being sometimes very scarce, at others so abundant as to mask the fibrous structure; sometimes regularly distributed, at others in the direction of the bundles and in their interstices, and again distributed at regular distances in the primitive cylinder, so as to present regularly disposed alternate transparent interstices in the course of the fibres.

Arriving at the fourth, or most perfect degree of development, the muscles of voluntary motion are met with from molluscs upwards to the highest classes. The line of demarcation, however, is not so clearly traced but that these most perfect forms are found in some polyps, molluscs, helminthoids, annelides, and radiates.

M. Lebert states that errors exist in the observations of other anatomists in reference to the structure of muscular fibre. By varying and greatly multiplying his observations and researches, M. Lebert believes that he has avoided these errors.

The muscular cylinder is, in its relation to muscular movements, the analogue of the primitive nervous tube in relation to the phenomena of innervation. It is neither the primitive fibre, nor the transverse marking, but the union in the muscular cylinder or fascicle, of those essential elements which constitute the integrity of the motor force in the most perfect form of muscle.

By "primitive cylinders" M. Lebert denominates every portion of muscular tissue that is clearly defined at its circumference, or which under the microscope presents two longitudinal aspects much more definite and isolated than the longitudinal fibres of their interior, and which, for the most part, exhibit transverse foldings. These cylinders are long, parallel, flattened from before backwards, grouped together, and united by cellular tissue to form muscular fasciculi.

There is one mode of grouping of these cylinders to which sufficient attention has not been paid: it is that of their union to the number of four or five, to form one secondary cylinder much more distinctly defined externally than the constituent primary fibres. These secondary cylinders are furnished with common sheaths, and cradled to those of

these contained primitive cylinders. Under these circumstances, two errors are to be avoided: one is, not to confound the *secondary* with the *primary* cylinder; the other, still more important, not to mistake the *primitive cylinders* for the *primitive fibres*. Either of these errors is a source of confusion in terms and measurements.

The muscular cylinder, then, is furnished on its surface with transverse folds, and involves the primitive fibres with their uniting medium, and their fibrillar and inter-fibrillar molecules.

The transverse folds are wanting in the fibres of the heart of the higher animals; and in some voluntary muscles of the very young of vertebrate animals. The substance of the heart appears to form an intermediate degree between the muscles of voluntary and of involuntary action—between those of animal and of organic life.

Histological evidence is not yet conclusive to that point, but there is every probability that it will establish the division of the muscles into those of animal and those of organic life.

To return to the surface of the cylinders. The transverse folds are not the effects of their contraction: they are permanent, although they approximate and recede according to the condition of contraction and relaxation of the cylinder. These transverse folds exist only on the surface; otherwise, by traversing the cylinder, they would divide it into a series of discs.

The primitive fibres in the cylinders are firmly united together: they are smooth, alternately opaque and transparent, owing to the arrangement of their granules; and, when arranged side by side, their juxtaposition gives the appearance of transverse folds.

The size of the primitive fibre fluctuates between 0 mm, 001, and 0 mm, 0015 (about 1-25,600th of an inch), and corresponds nearly with the diameters of the opaque granules.

The size of the non-striated cylinder varies from 0 mm, 004 (1-6400th inch), and 0 mm, 02.

That of the striated primitive cylinder from 0 mm, 005, to 0 mm, 1.

The distance of the transverse folds varies from 0 mm, 001, to 0 mm, 01.

The nerves are distributed by their primitive tubes between the muscular cylinders with which they lie in contact without penetrating.

With regard to the manner of the contraction of muscular fibre, M. Lebert repeats the statement of Weber, which his researches confirm.—*Gazette Médicale*. x

EXPERIMENTS ON ABSORPTION—INTRODUCTION OF INSOLUBLE SUBSTANCES INTO THE CIRCULATION. BY M. BERNARD.

SUBSTANCES that are capable of being absorbed may be divided into three classes:

1. Liquids or solutions.
2. Gaseous bodies.
3. Solids capable of minute division.

The last mode of absorption has been disputed; but M. Bernard states that he has shown this to be no less real than that of undissolved fatty matters.

M. Bernard has studied the subject of absorption in reference to the following points:—

What part do the nerves perform in this process? Is it entirely physical, and independent of nervous influences? Does the quantity of blood influence absorption? Does absorption take place in a bleeding animal with a rapidity proportioned to the loss of blood?

The stomach, when empty, absorbs freely; but when full, and in the act of secretion, it absorbs no longer. Absorption takes place generally where there are vessels, as in the lungs, the cellular tissue, the skin deprived of its epidermis; but nevertheless, there are substances which are not equally absorbed in all parts of the body, which will cause death when introduced into the blood or tissues, but are inert when introduced into the alimentary canal. A living or a dead membrane is only capable of endosmosis up to a certain point; after saturation the process will cease. Does carbonic acid produce asphyxia by its own poisonous nature, or by the impediment offered to respiration? An elective or specific absorption has been attributed to the lacteals. M. Bernard points out that the phenomena are due to peculiarity of structure of the lymphatics and veins of each intestinal villus. MM. Magendie, Segalas, Sandras, Bouchardat, and others, considered that certain substances pass from the intestines by the veins, and not by the lacteals. M. Bernard indicates an error, in their observations having been made on the contents of the portal vein and thoracic duct. If prussiate of potash be injected into the stomach, and the lacteals be examined as they pass from the intestines, the salt will be detected, and thence to the glands.

In order to illustrate the various modes of absorption, M. Bernard first treats of the absorption of poisons.

The poison of the viper is clearly not absorbed by the mucous membrane, or the animal would poison itself by the secretion of its venomous saliva. The same may be observed of the poison of rabies. A parallel fact is recorded by Humboldt.—The South

American Indians, in the neighbourhood of the Orinoco, have a poison (the *curare*, or *woorara* poison), collected from plants of the *Strychnos* tribe, and with which they poison the weapons used in killing animals; and yet these animals feed with impunity upon the plants from which the poison is derived.

M. Bernard at first supposed that this fact was to be explained by attributing its separation from the blood in the liver; but having injected a portion of this poison into one of the veins of the portal system, the effects of poisoning speedily followed, showing that the immunity resulted from some influence exerted upon the poison in the alimentary canal.

M. Bernard introduced a portion of *woorara* through a fistulous opening into the stomach of a dog, and administered also a portion by the mouth, without producing ill consequences. The gastric juice, under both circumstances, exerted a poisonous influence when inserted into the cellular tissue, rendering it evident that the *woorara* had not been destroyed by the chemical action of the gastric juice.

When injected into the rectum, or inclosed in a portion of intestine between two ligatures, the poison was absorbed without ill effects.

The analysis of the *woorara*, and of the poison of the viper, exhibits in each an insoluble substance, which M. Bernard regards as a ferment analogous to animal and vegetable diastase, or to pepsin.

M. Bernard gives the result of experiments made upon the action of *amygdaline* and *emulsine*—two substances which, separately, are inactive; but which, mixed together with water, form prussic acid poison of great potency. If administered to animals so as to combine in the course of the alimentary canal, no injurious effect ensued; but if made to meet in the cellular tissue, or in the course of the circulation, the phenomena of poisoning are immediately manifested, the odour of prussic acid being perceptible in the dead body.

The same occurs if the *amygdaline* be introduced into the digestive tube, and the *emulsine* into the blood, because the former is dissolved and absorbed; but the *emulsine* containing the insoluble ferment is not absorbed, and the poisonous effect does not follow if the latter be in contact with the mucous membrane.

Investigations into the phenomena of *endosmosis* reveal curious analogies with reference to the non-absorption of certain substances by mucous membranes. If an endosmometer, formed of animal membrane, be plunged into a solution of *woorara*, the water passes, and not the poison. If the experiment be tried on a solution of *prussic*

acid, the water will pass, while the *emulsine* remains. The diastase of a germinating seed is in the same predicament, because vegetable membranes possess similar properties. If a bean be placed in gastric juice or a solution of pepsine, it will become swollen by imbibition, and be capable of germination so long as its surface is unbroken. In this manner seeds taken into the digestive organs may retain their germinating powers, and be conveyed to great distances. But if the slightest fissure exist on its surface, the pepsine or diastase will enter its structure, and it will be digested. In a similar manner *amygdaline* and *emulsine* exist distinctly side by side in the bitter almond so long as its structure is entire: they are separated only by a thin membrane.

M. Bernard alludes to the absorption of vermilion and of Prussian blue from tattooed marks in the skin, and the detection of these substances in the neighbouring glands by M. Föllin. M. Starlin, he adds, has also detected abundant particles of charcoal in the lungs of animals to which that substance had been largely administered. These facts, M. Bernard considers, establish the absorption of insoluble substances by the lymphatics. The explanation of their manner of absorption is still wanting. Microscopical anatomy does not detect orifices in the villi of mucous membranes.

The explanation of these apparent cases of elective power of absorption in mucous membranes is simply a want of absorption: it is only the soluble portion which cannot be absorbed, while the insoluble portion is absorbed; thus reversing the doctrine—*corpora non agunt nisi sint soluta*. All substances not capable of absorption belong to the class of ferments or poisons.

M. Bernard mentions some facts from inorganic nature analogous to the preceding—*e. g.*, if a solution of acetate of copper be poured upon a filter of animal charcoal, the acetic acid will pass through, and the copper remain in the charcoal. In retention of urine the water is absorbed, while the urea becomes concentrated. The same is observed with reference to bile, which becomes inspissated on retention.

M. Bernard gives a new explanation of the phenomenon of the rapid appearance of certain fluids in the urine after their ingestion into the stomach. He has discovered that liquids, after having traversed the vena porta and the liver, and having arrived in the vena cava inferior, descend again by that vein to the renal veins; that there exists a valve in the interior of the vena cava, at the point of the orifices of the renal veins, which hinders the passage of the blood in the *ca* and the fluid is

obliged to pass by the renal veins, which thus for the time perform the office of arteries. This phenomenon occurs only when a large quantity of liquid has been drunk. The mechanism exists in all animals which take a large quantity of food of a slightly nutritious quality. If only a small quantity of fluid be taken, the circulation proceeds uninterruptedly towards the heart.

The lumbar and azygos veins form a collateral circulation by which the obstruction of the ilio veins is obviated. The communication of the portal circulation in the liver with that of the vena cava favours the rapidity of the passage of fluid, and forms a diversion for the relief of the heart against so sudden an increase in the quantity of the blood.

M. Bernard further points out the muscularity of the vena cava from the hepatic to the renal veins. This portion he regards as a true heart, which acts temporarily under the circumstances above indicated, while the valves before named prevent the flow of blood beyond the renal veins. The quantity of blood thus diverted passes by urinary secretion. M. Bernard remarks also that this arrangement of the circulation may explain the rapid disappearance of certain poisons in some animals. It may be regarded as the representation of the circulation in reptiles, where the blood of the lower parts of the body passes through the kidneys.—*L'Union Médicale.* 7

14. Violence, Privation, Cold, &c.....	26

The following is a selection of the numbers of Deaths from the most important special causes:

Small-pox	18	Convulsions	26
Measles	24	Branchitis	70
Scarlatina	39	Pneumonia	56
Whooping-cough	27	Phthisis	125
Diarrhoea	20	Lungs	8
Cholera	0	Testicles	7
Typhus	56	Stomach	4
Dropsy	8	Liver	12
Hydrocephalus	25		
Apoplexy	34	Childbirth	5
Furcalysis	20	Uterus	3

REMARKS.—The total number of deaths was 82 below the average mortality of the 40th week of the previous years.

METEOROLOGICAL SUMMARY.

NOTICES TO CORRESPONDENTS.

The letter of a Constant Reader and Subscriber is under consideration.

We are obliged to Dr. H. Fearnside for his communication. His request shall be attended to. We shall be glad to receive other papers from our correspondent.

Communications have been received from Dr. Pollock and Mr. Spence Bate. A private note will be sent to Dr. Pollock.

Mr. James Fisher's letter has come to hand. The subject referred to by Dr. W. Cholmeley is elsewhere noticed.

Lectures.

CLINICAL LECTURE
ON A CASE OF
ACUTE IDIOPATHIC TRISMUS.
(Delivered at King's College Hospital).

By R. B. Todd, M.D. F.R.S.
Physician to the Hospital.

[Reported by H. H. Salter, M.B., Dem. Anat.
K.C.L.]

LECTURE XIV.

GENTLEMEN,—Within the last day or two, as you are aware, a patient has died within the walls of this hospital of idiopathic tetanus, or, more properly speaking, of that form of it which, from the muscles of the jaws being chiefly affected, is called trismus (*tripsē, strido*); and, as this is comparatively a rare disease, and, in the majority of cases, a fatal one, I am anxious not to let an instance of it pass without making it a source of instruction to you, by giving you some account of its clinical history and pathology.

The patient, Henry Franklin, æt. 40, was admitted into the Sutherland Ward on Tuesday, November 6th. His history was this:—On Sunday, October 28th, he awoke with a swollen face, and some feeling of stiffness about the jaws: he attributed this to his having caught cold by sleeping with his window open. The feeling of stiffness increased, but he was able to swallow till Sunday, the 4th of November, seven days after the first accession of the symptoms; and since that time he has been unable to perform the act of deglutition. On his admission (Tuesday, 6th) we found him with his face very much swollen in the region of the parotids, and with considerable fetor of his breath; and we also found, on inquiry, that he had been taking some pills with mercury, though in small quantity, in them: it is therefore very possible that he may have been one of those persons who are affected by a small quantity of mercury, and that he was in a state of salivation.

We found also great rigidity of his masseter muscles, so as to prevent his opening his mouth, and, consequently, his either speak-

ing or swallowing. His teeth could at first be separated just so far as to slip in a card, but no farther. Moreover, we found that the effort was accompanied with great pain, which is always the case if tension is applied to a muscle in a state of contraction, as is seen in ordinary cramp, and in the treatment of club-foot: moreover, the attempt to overcome this contraction not only gave great pain, but also increased the spasm. It appeared that the muscles of deglutition were also affected, as he stated that the attempt to swallow his saliva nearly choked him.

Upon further inquiry we learned that his previous life had been temperate and sober; that he had had syphilis and secondary eruption, but no sore-throat, or nodes on his tibia or elsewhere; that he had never been subject to fits of any sort, but that he had had brain fever. This was the first day we saw him, and my apprehensions were excited as to the nature of the case: I feared it would turn out what it afterwards proved. But this supposition was very much negated by the absence of any manifest cause for tetanus. Excepting the exposure to cold, the slight salivation, and a small abrasion on the nose, occasioned by a fall which occurred the day before the accession of his first symptoms, there was nothing to which tetanus could possibly be assigned. The wound on the nose was very slight, and may be dismissed from the consideration at once. Cold is not an infrequent cause of tetanus in tropical climates, where the alternations of temperature are great; but it is a rare cause in this climate. I have witnessed one such case, in which the tetanic symptoms were attributed to the exposure of the patient to the open air during the whole of a very cold night. It is very possible that the exposure to the open window all night might have been the exciting cause of the disease in the present instance. Might the salivation have been the cause of the tetanus? There are on record some cases of tetanus produced by salivation. But it does not appear from the history of this case that the salivation was distinctly antecedent to the tetanic symptoms.

There was, then, a certain amount of obscurity about the case, and I was not quite prepared to act at once upon the notion that it was tetanus; I therefore adopted a treatment less decided than I should otherwise have pursued. I ordered him fomentations to the jaws and throat, an enema of starch and opium at night, and beef-tea enemata throughout the day: in fact, my treatment was very much of the expectant kind. I determined to see what the next day would produce, and

contented myself with dealing with the existing symptoms.

The next day we found the symptoms of spasm still the same. The jaw was firmly clenched, and attempts to open the mouth produced great pain. He was still unable to swallow his saliva, which frothed out of his mouth at each expiration. The secretion was certainly unduly abundant. All this time he was perfectly sensible, clear, and composed. He was not at all excited in his manner, and, although he could not speak, he understood all that was said, and wrote down on paper coherent and intelligent answers to all questions that were put to him.

Here, then, we had no symptom but the local affection of trismus, which might have been the effect of the local application of cold; but my fears were that it was but the early stage of a genuine case of lock-jaw, and I stated my fears to be such. I therefore determined to try tobacco fomentation, which I have frequently seen used, and with great advantage if care is taken to uphold the strength of the patient. Tobacco has this great disadvantage,—it is a very depressing agent, and therefore tends to throw the patient into that very condition which is the most fatal tendency of the disease. To avoid this, care should be taken to use the tobacco infusion weak, or the patient may be exhausted to a degree that may prove fatal.

At seven o'clock of the evening of this day, a symptom supervened which left no doubt as to the nature of the malady: it consisted in a violent paroxysm, throwing into active contraction, not only the muscles of the jaw, but also those of the neck, chest, and back, the last producing partial opisthotonos; the sterno-hyoid, sterno-thyroid, and sterno-mastoid muscles were thrown into a state of rigidity, and this condition implicated the muscles of respiration, and so far interfered with that function, that the patient felt as if he should be choked, and jumped out of bed to endeavour to get air. This choking sensation was not caused by any contraction of the glottis, but was due to the impeded action of the muscles of respiration: in fact, the man was kept in a constant state of imperfect respiration, or rather forced expiration, the consequence of which was that the venous system was thrown into a state of great congestion,—an interesting illustration of the way in which convulsion may give rise to congestion. The pupils were very much contracted during the paroxysm,—a circumstance of great interest, as showing a peculiar state of nervous centres connected with the excitement of the spasm; for, as soon as the spasm went off, the contraction of the pupils went off too; and, when the

spasm was at its height, the pupils were contracted to pins' points. The pulse during the paroxysm rose to 120.

From this time the case put on a more severe form: not only the permanent contraction of the muscles and all the other conditions continued, but every now and then one of the paroxysms would come on, each succeeding one being more severe and longer than that which preceded it; leaving the patient in a state of great exhaustion, and exciting in our minds the idea that he might be asphyxiated and die in one of them. If, however, there was any reason for such a fear, there was nothing to be done to obviate it; for, even had we performed tracheotomy, it would have availed little, for we should still have left the rigidity of the respiratory muscles unrelieved, which alone would doubtless have sufficed to produce asphyxia. But, in truth, death by exhaustion was the great thing to be feared: what we had most to apprehend was that which actually did take place—namely, that the increased frequency and severity of the paroxysms would at length produce a fatal exhaustion, and that the patient would sink rapidly after one of them.

The indication for treatment was therefore to support: and, since it was impossible to get the patient to swallow (the attempt being immediately followed by an exacerbation of the spasm), the only alternative was, in default of one entrance, to try another. I gave him, therefore, a drachm of sulphate of quinine, in a small quantity of water, as an injection, continued the beef-tea enemata, and being anxious, if possible, to diminish the pain and spasm, I ordered the frequent inhalation of chloroform,—the plan being to give it, not in large quantities, but in small and often-repeated doses, with a large admixture of air, so as to produce a gradual and soothing effect. By this means we were able to obtain resolution of the spasmodic condition of the muscles; but to arrest the paroxysms, or diminish their strength when on him, the chloroform seemed almost powerless.

At about a quarter to twelve, A.M., on the 8th, the quinine enema was repeated: at this time he was lying in an unconscious state from the chloroform (under the influence of which he was constantly kept), with his muscles relaxed, and breathing tranquilly. About five minutes after twelve a violent spasm came on, the jaws knocked together with a distinctly audible click, the face became much distorted and livid, the eyes rolled upwards, and there was much frothing at the mouth, and great apparent difficulty of breathing the sterno-mastoids violently contracted, and the head thrown forwards: in a minute or two

this was succeeded by a well-marked opisthotonos, the body being much curved, and resting on the occiput and sacrum. In this state he died. His death may be said to have taken place by asthenia, its immediate cause being exhaustion produced by the spasm.

There was nothing in the previous history of this patient to throw any light upon the case; he had been a sober man, had had syphilis and secondary eruption, and an illness which was called brain fever, but there was nothing to indicate any disposition to the malady of which he died—nothing, either in the man or the circumstances in which he had been placed, that could be considered predisposing to tetanus. So it is in all the cases of this disease we meet with: there is no connection between the previous history of the patient and the disease; the immediate exciting cause, and the detail of the symptoms, constitute the entire history of the case.

Of course I was very anxious to have a post-mortem examination, and it fortunately happened that we were able to have one under very advantageous circumstances; the examination being made only four hours after death, when, if there had been any morbid appearances, they would have been free from the fallacy of post-mortem change. There was, however, as I had anticipated, no morbid appearance which seemed to offer any explanation of the disease: the nervous centres, both brain and spinal cord, were perfectly healthy,—perhaps the brain contained a little more blood than usual,—a fact not to be wondered at when we consider the violence of

the paroxysms: the grey matter of the brain was perfectly natural, and its demarcation peculiarly distinct; perhaps, indeed, this remarkable distinctness may have been morbid, and may have indicated an undue functional activity of these parts.

I was very anxious to examine the state of the masseters, to see if any change had taken place in their ultimate structure, in consequence of the prolonged spasm which they had undergone. The result has been highly confirmatory of certain doctrines first laid down by Mr. Bowman, and remarkably illustrative of the way in which the contraction of muscle takes place. When a muscle is thrown into a state of contraction, that contraction does not affect the whole mass of the muscle, or even the whole of any of its fibres, at the same moment, but certain points or nodes are contracted; while the intervals are not merely passive, but are stretched by the contraction of the contracted portions; so that you have a succession of contracted points throughout the entire length of each fibre of the muscle. Now here you see a magnified representation, made by Mr. Salter, of two fibres, taken from the masseter of the patient, showing that peculiar condition which was first described by Mr. Bowman to exist in the muscles of persons who have died of tetanus, and which, as you will see, results immediately from the physiology of muscular contraction. You must not imagine that all the fibres were so affected: these were the two most marked specimens among many hundreds that were examined, some possessing the appearance in a slight degree, some not at all. Here you see the sarcolemma continuous

Two Fibres of the Masseter Muscle ruptured by the Tetanic Spasm.

m m separated masses of sarcous parietes; s s s sarcolemma.

throughout its entire length; but the contained sarcous matter is *not* continuous, but is broken up into isolated portions of various sizes, producing a peculiar bulged condition of the sarcolemma, with collapsed constricted portions in the interval. Now how is this appearance produced? Thus: each of the ruptured portions was the centre of a contraction at the time

when the muscle was in a state of violent spasm; the force of the contraction exercised at these points was so great that the tenacity of the intervening stretched portions was not sufficient to resist the divergent force: they gave way, and the particles thus isolated when in a state of contraction, having no antagonistic force to restore them when the contracting force had subsided, remain,

as you see them, in a state of permanent contraction, leaving intervals of considerable length between them.

I think, gentlemen, that these are all the points I have to call your attention to in the history of the case: and I will now make a few observations of which this history is suggestive.

First, with regard to the name: what shall we call it? Two names are in frequent use for such affections—*tetanus* and *trismus*. I prefer *trismus*, as being more specific, localising the affection, and showing its restriction to the muscles of the jaw. *Tetanus* is a more generic name, and indicates the general existence of tonic spasm, without any restriction as to its whereabouts. Tetanus can hardly be called a very rare disease: trismus occurring in the adult is a very rare disease. In the present case the affection was for eight days confined to the muscles closing the jaw; only within a day of his death did it extend to the muscles of the neck and back; and not till the very last stage did it so affect the muscles of the back as to produce opisthotonos: whereas, in ordinary tetanus, the extension of the spasm to all the muscles generally occurs very early in the disease: opisthotonos may be a prominent symptom for three-fourths the duration of the attack; and, if you put your hand on the arms or legs of patients so affected, you find them hard, knotty, and rigid; whereas, in the present case, the affection was limited to the jaws; and I therefore prefer to call it trismus. The only essential difference between the two diseases is in the extent of the nervous centres, and, therefore, of the muscles implicated.

Sir Benjamin Brodie has instituted an excellent practical distinction between *acute* and *chronic* tetanus—the one running a short course, with strongly marked symptoms, and terminating always fatally; the other of longer duration, milder form, and frequently recovered from. Traumatic tetanus is very apt to be acute; but tetanus, however caused, frequently puts on a chronic form. Some of these cases last twenty days or more; and, when prolonged in this way, there is great hope of ultimate recovery. If such a case—or still more, if two or three such—should happen to fall into the hands of some very zealous supporter of any particular practice—if he is a great bleeder, or a free giver of opium—the treatment is immediately set down as specific, and the recoveries are appealed to in proof of its infallibility, the real secret of the successful issue being that the cases were chronic, and not acute. Now in the case of our patient it cannot possibly be said that anything was done to shorten life: possibly the means adopted for its

prolongation might have been more energetically plied; the quinine might have been earlier administered, and perhaps more support might have been given: still nothing was done that could by any possibility have accelerated the fatal termination of his disease. Yet we see him admitted into the hospital on the Tuesday with but slight symptoms of the disease, and dead on the Thursday morning. And this is an essential part of the natural history of all these acute cases—speedy and fatal termination, death taking place by exhaustion.

The peculiar points in this case that especially call for remark are, the violence of the spasm, and its restriction for so long a time to the jaws. As I said just now, genuine trismus is rare in adults. In newly-born infants, however, trismus is not rare, particularly in hot climates: in the West Indies it used to be very common: it goes by the name of *trismus nascentium*; and though now, from greater care in food, cleanliness, and ventilation, it is much less frequent than it was, it even yet carries off a great number of children.

I have said that this case illustrates the mode of death by exhaustion: this is an important point, and one I particularly wish to impress upon you. Death does not take place by asphyxia, nor by any particular effect on any special organ, but from general exhaustion, induced by the protracted and unwonted muscular exertion. This, I think, is not sufficiently attended to in the treatment both of this and of many other diseases.

The case also illustrates the little hope we have of obtaining any information, either practical or pathological, by post-mortem examination of the particular state of the nervous system: we can only draw our conclusions as to the pathology of the disease from our knowledge of the physiology of the parts concerned. Now, reasoning on this principle, it may be laid down that the phenomena result from an exalted polarity of the centres supplying the parts affected. In the case of traumatic tetanus, the exaltation of the polar state commences in the afferent nerves of the part that is the seat of the wound: if the tetanus arises from cold, the exalted polarity commences in those nerves of common sensation distributed to the exposed part: from the periphery thus irritated the condition is propagated through the nerves to the centres, and the effects on the muscular system show to what portions of the nervous centres the exaltation of the polar force is communicated. This, however, does not fully explain the production of tetanus; for peripheral nerves, and even nervous centres, are often subjected to great irritation without giving rise to

tetanus; and it is well known that it is impossible, even by severe mutilations, to produce tetanus in the lower animals: whereas a slight accidental injury (as when a horse picks up a nail) will often produce the disease in its worst form. It would seem that some peculiar state of the system—probably some peculiar condition of the blood—is a necessary precursor of the disease. Hence, no doubt, its greater frequency in warm and unhealthy climates, in over-crowded and ill-ventilated military hospitals, and, among ill-housed, ill-fed infants.

That tetanus may be produced through the blood is shown by the results of the administration of strychnine, which exactly imitate the tetanic symptoms in every respect: so that you may at will develop the phenomena of tetanus in an animal by giving him strychnine, or injecting it into his blood, but you cannot cause it by external injuries.

What was the exact portion of the centres affected in the present instance? The localization is pretty clear: it was evidently the upper part of the spinal cord, the medulla oblongata, and its upward prolongation in the cranium, especially in the neighbourhood of the implantation of the fifth nerve. Indeed, the supposition that the disease was caused by the salivation would afford a very plausible explanation of the localization of the morbid action in this latter region; for in ptyalism the seat of the peripheral irritation must necessarily be the sentient filaments of the fifth nerve, which would, of course, propagate the irritation to the centre, and excite a similar state of the motor nerves, thereby giving rise to the spasmodic condition of the muscles of mastication which are supplied by the same nerve.

And we may ask, further, what is the nature of the morbid process set up in these centres? To this it may be confidently replied, as the result of repeated examinations, that it is not inflammation, nor anything allied thereto. And it may, with quite as much certainty, be affirmed that it is a state identical with that which strychnine is capable of producing. Now this state does not reveal to the most careful observation any appreciable departure from the normal state. I have repeatedly examined with the microscope the spinal cords of animals killed by strychnine, and have never been able to detect, even with the highest powers, the slightest morbid chan-

The condition of the nervous system in tetanus is, as it seems to me, best described by the term *exalted polarity*,—which favours the undue development of the nervous force. A peculiar state is, that whilst the polar

nervous centre is at all times exalted, it is liable to frequent fits of augmentation or exacerbation, during which more extensive effects are produced. In this way we explain the absence of any affection of the spinal cord for a considerable period, and the subsequent excitation of it in consequence of severe paroxysms affecting the medulla oblongata and its prolongations.

Now, if we were to meet with another case, what treatment should we adopt? I do not know that I should pursue any different treatment from that which I have described to you as having been adopted in the case of our patient Franklin. I might, perhaps, give support earlier than I did in the present case. I should give a large quantity of quinine by the mouth or rectum: if there were much difficulty of deglutition, I should throw up beef-tea enemata freely, and I should administer chloroform carefully. The great danger of chloroform is that it depresses: now, in tetanus you ought to husband and augment the strength of your patient as much as possible; the disease itself depresses enough; and an important aim in your treatment should be to enable your patient to sustain the reiterated shock of his spasms: therefore, if you give him chloroform, take care at the same time to support him well, and be not afraid of giving him stimulants—such as wine or brandy—if you think he can digest them, and especially if the difficulty of swallowing prevents the patient from taking more than a small quantity of nutriment at a time. The cases that I have known succeed the best have all been treated with close attention to upholding the powers of the patient. If you bear in mind that the great danger is of death from exhaustion, and act accordingly, you will not go wrong in this particular. There is no use in blood-letting in cases of this kind, as frequently practised formerly, nor in active purgation: the bowels, however, should be evacuated daily, or on alternate days, but more than this is prejudicial. There is also no good to be derived from giving those excessive doses of opium that have been used in so many cases; for, besides the negative evidence of its inutility, there is this objection to the practice—that opium given in large doses tends to call forth that very exaltation of the polarity of the nervous system which we desire to combat. This is abundantly proved by experiments on cold-blooded animals. You may throw a frog into

opium; and although so it is produced by opium animals, many circumstances that it may give rise to much less in de-creases in reptiles. It is good from hydro-

cyanic acid? I think not: and my objections to it are much the same as those against opium—viz., that it tends to exalt, and not to lower the polarity of the nervous system. Those of you who have seen the death of an animal from hydrocyanic acid will at once appreciate this objection. You will remember the violent epilepsy—the tetanic epilepsy, if I may call it so,—the combination of tonic and clonic spasm, under which the animal suffers.

The use of galvanism has been proposed in cases of this description for the purpose of depolarizing the nervous centres, and has actually been tried by Matteucci. The long-continued passage of a current of galvanism tends to weaken and to paralyse a nerve or nervous centre, if the direction of the current be the same as that of the nervous force. In the case related by Matteucci the spasmodic condition of the muscles completely subsided during the passage of the electric current.

Another part of our treatment was the application of cold over the region of the spine. Cold has a powerful effect in depolarizing the spinal cord. I have tried it with great advantage in this hospital in tetanus, in laryngismus, and in the convulsions of children. The best plan is to fill a bladder with some broken ice, and apply it directly to the spine: an intense degree of cold may be thus obtained in a very short time, and its effect on the circulation will soon be manifest, cold having a very powerful influence in diminishing both the force and frequency of the heart's action: for this reason you must not apply it too long, or too much of it; you must watch your patient, and remove it and reapply, as his condition shall indicate. The cases in which I have tried it I have found manifestly benefitted by it in diminishing the intensity of the spasms.

With regard to internal remedies, I know of nothing better than small doses of opium, belladonna, and conium. The two latter drugs certainly seem to me to have a depolarizing power, as is sufficiently obvious from their influence, especially that of belladonna, in causing dilatation of the pupil. Still, a good depolarizing agent which does not tend at the same time to weaken or depress the powers of the patient, is a great desideratum, and when discovered will no doubt prove an invaluable remedy in the treatment of tetanus. What, however, in the absence of such a remedy, the physician has principally to trust to is to support, in order that he may gain time, to enable his patient to weather the storm, and to sustain the attacks of his disease till the source of irritation shall have ceased to exist, and its consequences have abated.

I must not conclude without calling your

attention to the great importance of isolating tetanic patients, and protecting them, not only from the excitement caused by many persons surrounding the bed, but also from the influence of draughts or currents of air, or external mechanical stimuli, which are peculiarly prone to excite the tetanic spasm. These patients ought always to be put into a separate ward, and visitors excluded as much as possible. The temperature of the room should be kept at a moderate degree, and care should be taken to exclude sound, irregular currents of air, and light, as far as it can be conveniently done.

MEDICAL EDUCATION IN PHILADELPHIA— THE FEMALE MEDICAL COLLEGE.

THE New York Medical Gazette informs its readers that this College has commenced its session, and, as we learn, some forty or fifty *women* were in attendance as students, a much larger number of the sex having been present at the introductory lectures. The Faculty are all males, and, we learn, are pledged to give place to females as soon as their fair pupils shall, under their instructions, become qualified as teachers in the several departments. The gentlemen occupying the several chairs at present are plain men of mature age, and appear to appreciate the novelty and difficulties of their undertaking, in which, however, they seem to be very soberly in earnest. We have heretofore expressed our misgivings in regard to the *morale* of this enterprise, but we see that "Professor Longshore," a prominent member of this Faculty, announces as the subject of his introductory lecture to *female students*, "*The immorality of obstetrical practice being conducted by men*." He seems to have overlooked the "*immorality*" of his own proposition with his male colleagues, to demonstrate to *women* the healthy and morbid anatomy of the sexes, and discourse before wives, widows, and maidens, old or young, upon topics in relation to which an inspired authority has taught that "they should not be even once named among you;" obviously meaning in a promiscuous assembly.

We cannot envy the task self-imposed by these teachers, and we cannot refrain from the expression of our pity for their infatuated pupils. We opine that both the one and the other will become heartily ashamed of their imbecility and folly, and repent hereafter for their mispent time and labour, if no worse mischiefs result from their association as teachers and pupils. We saw in their museum objects upon which no modest woman can look without a blush in the presence of the other sex, nor any virtuous maiden study under the teaching of men without mutual impurity and moral deterioration.

A BRIEF SKETCH OF THE MORE IMPORTANT
FLUCTUATIONS IN OPINION WHICH
HAVE PREVAILED AMONG
PRACTITIONERS OF
MIDWIFERY

WITH REFERENCE TO THE PERFORM-
ANCE OF TURNING;

AND THE

APPLICATION OF THE FORCEPS
IN CASES REQUIRING
ARTIFICIAL DE-
LIVERY,

ON ACCOUNT OF DEFORMITY OF THE
PELVIS.

By CHARLES WEST, M.D.

Physician-Accoucheur to St. Bartholomew's
Hospital, and Lecturer on Midwifery in the
Medical College.

It is almost superfluous to remind the reader that, previous to the invention of the midwifery forceps, there were but two proceedings generally adopted in cases where either the protraction of labour, or the supervention of some symptom threatening the well-being of the mother or her child, indicated the propriety of artificial delivery. These two proceedings were *embryotomy* and *turning*; for even the *Cæsarean section* had been at that time so rarely performed that it scarcely took rank among the recognised operations of obstetric surgery.

Since the re-discovery of the operation of turning by Ambrose Paré, it had been the constant endeavour of practitioners of midwifery to bring that operation to perfection. By degrees they extended the number of cases in which they resorted to it; and at length, practice having given many a great dexterity in its performance, they employed it in numerous instances of head presentation, where either feeble uterine action, or mechanical disproportion, retarded the labour, as well as when the occurrence of hæmorrhage or convulsions indicated the necessity for speedy delivery. Of all who distinguished themselves by thus extending the operation of turning, and reducing the performance of *embryotomy* to a minimum of frequency, La Motte is unquestionably the

most remarkable; and he closes worthily the list of those who, before the forceps were invented, signalled themselves by their endeavours to bring the obstetric art to perfection.

At the time when this new instrument was introduced into midwifery practice, its exercise both in England and Germany was to a very great degree in the hands of women; and its principles and practice were, as might be expected, more barbarous than in France, where it had already, for fully half a century, been customary in the better ranks of society to employ men not in difficult cases merely, but also in cases of natural labour.

In England, the first practitioner (after the Chamberlains, who made a secret of their discovery) who employed the forceps in practice, seems to have been a Mr. Drinkwater, of Brentford, who died in the year 1728. Giffard, who died only three years later (1731) also employed it; but the first public printed description of the instrument, and its mode of application, was given by Chapman, in the year 1733. English practitioners employed the forceps as one means of carrying on the war which at that time they were waging with the midwives. Proof of this is not only given us incidentally by Sterne, in his account of all the mishaps that attended upon Tristram's birth, but it is even apparent in Smellie's writings, who speaks of the practitioner as applying the instrument out of the nurse's or midwife's sight, beneath a sheet which was thrown over the bed, while its corners were sometimes pinned to the shoulders of the operator.* It was the grand *cheval de bataille* of the doctors—a means unknown for some time at least to the midwives, and the introduction of which had a great share in driving the latter from a very lucrative kind of practice. It is not to be wondered at that, under these circumstances, the forceps came into general use in England, and that there was comparatively little inquiry as to whether any class of cases would still be better treated by the old mode of turning than by the new one of applying the forceps.

Probab

much
and
the

seen at p. 50-51 of the Introduction to his Treatise on Midwifery. The great caution which Smellie observed in advising the employment of the long forceps, and his general recommendation of his short forceps only, coupled with his discountenancing the operation of turning in cases of difficult or protracted labour, had no doubt a great share in bringing about that frequent employment of embryotomy which was, and is still, in a measure, a characteristic of British practice. The quarrel between Smellie and his assistant Mackenzie, which ended in their separation, probably contributed still further to bring craniotomy into practice, since Mackenzie, influenced to some degree perhaps by his quarrel, decried the forceps, which Smellie, on the contrary, recommended. W. Hunter's teaching and practice tended in the same direction; and the just opposition which he made to bringing down the feet in breech cases led him still further to oppose turning in cases of difficult labour, and prepared the way for the general spread of those doctrines of which Dr. Osborne may be taken as the great representative and advocate; for though he recommended the forceps in preference to the lever, yet the tendency of his teachings was to increase the frequency of embryotomy.*

The influence of these teachings, however, was not so extensive but that many practitioners, long after the invention of the forceps, continued to turn in many cases of difficult or protracted labour. Thus, for instance, Dr. Baudenell Extor, who was physician accoucheur to the Middlesex Hospital, and the third edition of whose "Midwifery," published in 1753, is now before me, fancied that, when the head was low down, he could give safer and more efficient assistance with his hand than with forceps; and that, when the head was higher, it was preferable to deliver by turning. Mr. Pugh, of Chelmsford, whose book bears date 1754, though he invented a pair of curved long forceps, and gives very good directions for their application, yet recognised the existence of some cases of protracted labour in which turning was

to be resorted to: he mentions especially, at p. 78, that when the pelvis is too small or distorted, the head hydrocephalic or very much ossified, or its presentation wrong—"In all these cases, provided the head lies at the upper part of the brim, or though pressed into the pelvis, it can without violence be returned back into the uterus, the very best method is to turn the child and deliver by the feet, according to the directions already given." He then goes on to lay down the conditions which would induce him to prefer the curved forceps, and states (p. 77) that, as the result of these two modes of assisting the parturient woman—"I have never opened one head for upwards of fourteen years."

It will probably suffice to mention two more writers of this period, as showing that the introduction of the forceps into practice did not prevent many from duly weighing the advantages, or supposed advantages, of turning. Dr. Fielding Ould, in his Treatise on Midwifery, published at Dublin in 1742, while he speaks at p. 153 of "the large forceps, which is in general use all over Europe," and gives very sound directions as to its employment, at the same time suggests (p. 86-87), though he confesses that he never practised, the turning the child early in labour, and extracting it by the feet, in any case where the contraction of the pelvis had in a previous labour "refused an exit to the child (though not of an extraordinary size) by means of the common efforts of nature; and that on this account it died, or was destroyed by instruments, for the preservation of the mother's life."

He notices the objections that may be urged to this proceeding; but alleges that, though it is an interruption to the usual course of nature, still it is a less objectionable interference than would otherwise become necessary. "Again, it may be objected that the same narrowness of the passage through the pelvis which hindered the natural expulsion with the head foremost, may hinder its extraction when brought forth by the feet: this is also allowed; but yet, if we consider the matter properly, it will appear that, by drawing from a small end, which is the feet, in order to bring forth the larger, with the additional assistance of holding the legs in one hand, and having the finger

* Much interesting information as to the opinions and practice of the leading accoucheurs in London at the end of the last century will be found in Fischer, *Bemerkungen über die Englische Geburtshülfe*; Göttingen, 18mo. 1797.

of the other in the child's mouth, there is a far greater probability of bringing it forth than when the large end comes first, and that without any probability of assisting the mother's efforts but by the destruction of the child."

Burton, whose work on midwifery was published in the year 1751, advises, on the same grounds with Ould, the same proceeding, and speaks as if he had adopted it. To the directions, however, given by Ould, Burton adds at p. 168,—"and then turn the chin so as to pass the bones into the pelvis in the most commodious manner."

Enough has already been said to show that practitioners in this country were not blind to the advantages which turning might be supposed to present in some cases of protracted labour. It fell, however, more speedily into disuse in this country than in many parts of the continent, owing, in measure, probably to the same influences that have already been referred to as stamping a peculiar character upon operative midwifery in Great Britain, but also still more, in all likelihood, to the fact mentioned by Dr. Denman,* "That this practice was in general very unfortunate in the event, as I have been assured by some who have used it;" "yet," he adds, "cases may occur in which, by turning the child, the chance of saving its life is greater than can be gained by the use of any instrument." He then relates a case in which by adopting this proceeding he delivered a woman of her eighth child alive at the full period, all her other children having been still-born, and he himself having delivered her of her first two by means of instruments, which the deformity of her pelvis rendered necessary. This case is further interesting, from the circumstance of the left parietal bone having presented a depression, an inch deep, caused by the projection of the sacrum, which, however, by degrees disappeared. The woman recovered, without any untoward circumstance.

Dr. Denman concludes this section of his book, with the following estimate of turning under such circumstances:—

"But the success of such attempts to preserve the life of a child is very precarious; and the operation of turning a child under the circumstances before stated is rather to be considered among

those things of which an experienced man may sometimes avail himself in critical situations, than as submitting to the ordinary rules of practice."

Dr. Dewees,* the great obstetric authority in America, devotes a section of his work to "Turning in a deformed pelvis, as a means of saving the child's life." He decides that less than 3½ inches in the antero-posterior diameter of the pelvic brim would give no chance to the child, and even that size but a very slender one; though it may be right to adopt it when the practitioner feels hesitation as to the propriety of perforating, since "it gives a chance, though a forlorn one, to the child." He notices the different conditions essential to the successful issue of turning as far as the child is concerned, and remarking on the little likelihood of their being fulfilled when the pelvis is contracted, concludes, in words not unlike those of Dr. Denman, "that it must ever be looked upon as a doubtful alternative, rather than a probably safe resource."

Notwithstanding the evidence which La Motte's writings afforded of the successful performance of turning in many cases of protracted and difficult labour, the introduction of the forceps into France seems to have brought it even more into disuse than in England. The circumstance of Levret's forceps, being longer even than Smellie's long forceps, and that the former eminent man did not, like his English cotemporary, either employ or recommend a shorter instrument, probably had a great influence in bringing this about. With Levret's forceps practitioners were able to interfere while the head was still high in the pelvis; and if such interference failed, they had recourse to the perforator. Levret's protracted career, his wealth, and his position as accoucheur at the Court, all tended to give to his doctrines and practice a very great weight; and he disapproved of turning in cases where the pelvis was contracted, though he advocated its performance early in labour in cases of head presentation in which the head presented in an unfavourable position.† Levret survived till the year 1780, at which time Baudelecque was thirty-four years old, and had already distinguished himself by

his opposition to the practitioners of Sacombe's school, and to the advocates of the Sigaultian operation. The influence which Levret had exerted was exercised by Baudeloque, and in great measure continues even at the present day; and he not only held doctrines concerning obstetric operations similar to those of Levret, but, by adding two inches to the length of the forceps, sought to make that instrument even more universally applicable than it had been in the hands of his predecessor. Still, Baudeloque, so far from rejecting the operation of turning, expressly sanctions it in some cases of head presentation. "The bad conformation of the pelvis sometimes prescribes it; but almost all those who have advised and practised it on this account have not taken into consideration as much as was necessary the degree of disproportion between the dimensions of the head of the child and those of the pelvis of the mother: so that for one whose life has been saved by this means a great many others have been destroyed. This method is at best suitable only for those cases in which the want of space that interferes with the patient's delivery is but slight; when it is more considerable it necessitates the employment of the forceps, of crotchets, or even the performance of the Cæsarean section, &c., as will be shown in the fourth part of this work."

"It is not for the sake of adding to the expulsive efforts of the patient by dragging at the feet of the child, and afterwards at the other parts which precede the head, as many accoucheurs do, that the operation of turning should be undertaken, when the contraction of the pelvis, though but very slight, prevents the head from entering it. The peculiar structure of the foetal head indicates plainly enough the principles in accordance with which this operation can be performed with hope of success. The structure of the head is such, that it collapses more readily in proportion to its dimensions, and enters the pelvis with greater facility when the child comes footling (provided it is directed properly), than when the head is the presenting part, though a great number of accoucheurs think the contrary, and are of opinion that it then presents its widest diameter at the pelvic strait.*

It is needless, for the further elucidation of his views, to carry these extracts further, though the next fourteen pages are occupied with directions as to the mode of performing the operation of turning in cases of head-presentation.

Madame Lachapelle, however, so far from acquiescing in this merely occasional and exceptional substitution of turning for the forceps, in cases of contraction of the pelvis, gives it decidedly the preference. After pointing out the direction in which it would be desirable that the forceps should grasp the foetal head in cases of pelvic deformity, so as to accommodate its smallest diameter to the contracted antero-posterior diameter of the pelvis, she observes* :—

"It is doubtless to the greater facility with which we can direct the head of the foetus, and to the slighter compression of this part, that must be attributed the greater frequency with which, contrary to the opinion of many authors, I have succeeded in cases of this description by performing the operation of turning than by the application of the forceps. As may be seen by a reference to the tables already quoted,† of 15 children extracted by the forceps on account of a contracted state of the pelvis, 8 were still-born, 7 were born alive; while of 35 delivered footling, 16 were born alive, and only 9 were extracted without any sign of life. The proportion of cases in which turning proved successful amounted, then, to two-thirds, while the forceps succeeded in less than half." Madame Lachapelle then specifies, as another advantage of the operation of turning, "that it affords the means of ascertaining whether the child is living or dead, and consequently supplies data that may decide us to prefer, in a case where its extraction is found impracticable, either synchondrotomy or perforation of the head. With moderate care, the separation of the head from the body will not occur, and a crack, such as that which announces the giving way of the spine, sometimes takes place as the result merely of the sudden yielding of the bones of the cranium, and of the consequent descent of the head into the pelvic cavity; when, it need hardly be observed, it is a good sign, not a bad one."

† The tables appended to vol. i. and ii. of this work.

* *L'Art des Accouchemens*, p. 57 2-73, 7ième ed. Paris, 1833.

Finally, she takes leave of the subject with a recommendation of the operation of turning in cases of contraction of the transverse diameter of the pelvic outlet, as being preferable under such circumstances to the application of the forceps.

I should now proceed, as briefly as possible, to relate the opinions which have at different times been entertained with reference to the performance of turning in cases of pelvic deformity in Germany, were it not that some mention of M. Velpeau's opinions and practice becomes necessary, owing to an oversight on the part of some gentlemen of very high and deserved reputation who have coupled his name with the first adoption of this operation under these circumstances. In speaking of those cases of pelvic deformity in which the contraction is confined to one oblique diameter, M. Velpeau notices* how the same woman may in one pregnancy have a very easy, in another a very difficult labour, according as the head entered on the former occasion in the uncontracted, on the latter in the contracted diameter of the pelvic brim. In such cases the operation of turning affords a very easy way of overcoming the obstacle, since it allows the operator to direct the child's head into the most favourable position; of which a case that occurred in his own practice is cited as a very good illustration. In adopting this proceeding, however, M. Velpeau does not lay claim to any originality, while his own opinions, expressed in other parts of his work, show him to be on the whole opposed to the performance of turning in cases of head presentation. He remarks,† that practitioners differ as to the course to be pursued in cases where the head is still moveable about the pelvic brim. "Some, as Levret, Smellie, Plenk, and especially Flamant, are of opinion that the forceps offers greater advantages than the operation of turning. Others conceive with Madame Lachapelle, Desormeaux, and almost all modern writers, that the opposite is the case. Both, I conceive, are to a certain extent in error." He then points out the nature of these errors; his own view of the matter being that the forceps are safer for the child, the operation of turning the less hazardous

proceeding for the mother. He sums up thus:—"The wisest course lies between these two extremes; to prefer the forceps, if the practitioner is dexterous in employing them, if no great difficulties interfere with their application, and there be no risk of injuring the woman. On the other hand, under opposite circumstances, the operation of turning is to be preferred; that is to say, when the head is too high, or too moveable to be readily grasped by the forceps, and when no obstacle exists to the performance of turning."

The case of contraction of the oblique diameter of the pelvis being the only one in which M. Velpeau counsels the operation of turning as a means of overcoming the difficulties arising from pelvic deformity, it is perhaps not unfair to regard him, after the manner in which he expresses himself concerning this operation in the passage just quoted, as generally unfavourable to its employment in cases of disproportion.

Although at the present day more frequent use is made of the midwifery forceps in Germany than elsewhere, yet that instrument did not at first obtain by any means such ready acceptance there as either in England or France. Obstetric practice in Germany was, during the first half of the eighteenth century, almost entirely in the hands of midwives, who were accustomed to perform all except instrumental operations, and to treat the diseases of pregnancy, of the puerperal state, and of infancy, appealing but seldom to medical men. Ignorance on the part of the latter was the unavoidable result of the want of opportunities for observation,* while the sound teaching of such men as Stein and Roederer exerted of necessity a much narrower influence, from their positions in the universities of small states as Hanover and Hesse, than that of Levret did in France.

The forceps at first introduced into Germany, though known as the "English forceps," were the straight forceps of Grégoire,† and their use was limited,

as from Puzos' own expressions* would seem to have been the case also in Paris before the time of Levret, in which the head was situated quite low down between the rami of the pubes. The publication of such writings as those of Deisch and Mittelhäuser, in which embryotomy was recommended and had confessedly been repeatedly performed by themselves on most inadequate grounds, while it proves to how great a degree the uses of the forceps were unknown, may account also, by the revulsion of feeling which this barbarous practice excited, for the disinclination to all kinds of instrumental interference which seems to have existed in Germany during many years after the forceps were in general use in France and England. No one could be better fitted than Roederer, the pupil of Levret and Smellie, for the task of laying down right principles in operative midwifery; of his merits in which respect his *Opuscula Medica* afford more abundant evidence than his short *Elementa Artis Obstetriciæ*. The tendency of his teaching was to inspire confidence in the use of the forceps, to introduce them into practice in cases of irregular positions of the head, or sometimes to substitute for them the lever; at the same time to define the conditions in which embryotomy was justifiable, and while advocating turning in cases of transverse presentation, in which Mittelhäuser had very often most unwarrantably performed embryotomy, to restrict the frequency of its employment as a means of terminating protracted or difficult labours. He did not, however, institute that formal comparison between the merits of the forceps and turning with which his pupil Stein began his career as a public teacher. In the year 1768, he published as a sort of preface to the announcement of his lectures, an essay "*De Versionis negotio pro genio Partus salubri et noxio vicissim*;" in which he treats of the contra-indications to the operation, and points out the superiority of the forceps of his own instructor Levret, in the management of some of those dangerous complications of labour for which turning was generally practised. Among the conditions which, in his opinion, should forbid the performance of turning, he especially dwells

upon the existence of disproportion between the head of the child and the pelvis of the mother.* He concedes the value of Levret's suggestion in those cases for bringing the small diameter of the head into the small diameter of the pelvis, and directing the large diameter, contrary even to what might have been the natural course of the head, into the large diameter of the pelvis; but yet there are instances in which even this is unsuccessful, and then the use of the previously despised forceps becomes unavoidable, or perhaps even the perforator and cruetet are found to be necessary to the patient's delivery. He concludes, that where the want of space depends on the greater size than usual of the head, or the narrowness of the pelvis, provided this be not extreme, the forceps will usually suffice to effect delivery, even though the head had not entered the pelvic brim; while when the forceps cannot suffice, either craniotomy, or, in extreme cases, the Cæsarean section must be resorted to. The experience of the ensuing eight years only deepened the conviction expressed in this essay, and in 1773 he published another. "*De præstantia Forcipis ad Servandam Foetus in Partu Difficili Vitam*." In the second paragraph of this dissertation he proposes the question, to which he intends to reply, in these words:—"Whether, in a difficult labour, a greater number of children are or can be saved by means of Levret's forceps, or by the hand alone,"—i. e., by turning? This inquiry, he says, is one of great moment, and the off-hand decision of which in favour of turning, indicates both ignorance and presumption, for it is by no means every person who is competent to reply to it. Neither, indeed, is it by any means a matter of indifference which of these two modes of effecting a patient's delivery is selected; but the good of mankind, and the interests of the obstetric art, alike require that a positive decision be arrived at. He himself endeavours to answer it, as he says, partly by *a priori* reasoning, partly by inference from facts observed. He sets

* This and several other dissertations by Stein were translated into German, and, with some short essays originally published by him in that language, were collected by him into one volume, under the name of *Kleine Werke zur praktischen Geburtskunde*, 8vo. Marburg, 1798; in which see p. 366-70, §§ ix. x. for Stein's opinion concerning turning in the deformed pelvis.

* *Traité des Accouchemens*. Paris, 4to., 769, p. 131.

out by showing, that while the most natural of all cases of labour are those in which the head presents, it yet is not desirable to interfere with the course which nature may in any case adopt, so as to convert a case of footling presentation (though confessedly unfavourable) into one of head presentation, albeit that is the most favourable. If, then, it be unwise to interfere for the purpose of converting the worse into the better, it must be still more injudicious to interfere with the view of converting the better into the worse. This somewhat strange theoretical reasoning he supports by the allegation, that from the very structure of the head, it must pass the pelvis more easily when it comes first than last; for while* in the former case the pelvic brim is occupied by the yielding vertex, the different parts of which are united by sutures, it is in the other case filled by the unyielding basis cranii: so that it may be fairly concluded that the child which would be born with difficulty with its head presenting would be born with far greater difficulty if the head came last. Further, the dangers to the child are much greater in footling cases than in those where the head presents. To prove this, he publishes a list of all cases in which, during the previous ten years, he had either applied the forceps or turned, excluding from his reckoning all instances in which the delivery was premature, or the child, before the performance of the operation, was certainly known to be dead. This list gives a total of 54 forceps cases, in which 41 children were born alive, and 13 born dead; while 66 cases of turning yielded 33 children living, and the same number still-born.

Of all the pupils of Stein, the elder Oslander is he who exercised the greatest influence upon the practice of midwifery in his own country. With great, probably too great, fondness for operative interference, he entertained to the full his teacher's preference for the use of the forceps in all cases where disproportion exists. That this opinion, too, was not adopted without full deliberation, is sufficiently attested by the very carefully written chapter in his work on midwifery "upon the Influence

of the Forceps, and of the Operation of Turning upon the Mother and Child." In a note to this chapter,* and more fully in another work, he mentions that between the years 1782 and 1792 he applied the forceps 39 times, and had 78 cases, either footling from the outset, or in which he performed the operation of turning. In 33 out of the 39 forceps cases the children were born alive; while of the other 78 cases only 37 yielded living children,—a fatality indeed, which, he says, greater dexterity obtained by practice in subsequent years enabled him to diminish, though it does not appear to have modified his opinions. He did not, indeed, himself complete his large work on midwifery, but his principles are laid down most positively in a condensed form in his *Neue Denkwürdigkeiten*. In the last volume of this work, published in 1799, he sanctions, p. 105, the performance of turning, provided the head be still high up, and the pelvis well proportioned; but he adds, that the indications are very different if the pelvis be contracted. "If the pelvic brim be considerably contracted, turning ought not on any account to be performed, for it will certainly be attended with great difficulty, and lead to a bad result; and at the very best, the life of the child will almost certainly be lost." Under these circumstances, then, he advocates the use of the forceps; but if the brim of the pelvis be capacious, and its outlet only contracted, he counsels the operation of turning, coupled with the subsequent application of the forceps if necessary. "The reason," he says,† "why the head can thus be more readily got through the pelvis is, that when it enters the pelvic apertures in this position, with the chin depressed upon the chest, it forms a wedge whose apex is directed towards the cavity of the pelvis; while at the same time, by holding the feet, and making traction by them, the head can be firmly fixed, and thus prevented from slipping out of the grasp of the forceps."

Oslander's contemporary, and the most formidable opponent of his somewhat too meddling practice, the late Professor Boer, of Vienna, expresses

* The meaning of the writer is here somewhat obscure, but I believe that I have stated it correctly. See § 10 of the German translation, which alone I possess.

† *Handbuch der Entbindungskunst*, 2te Aufl. Tübingen, 1830; 2ter Band, S. 363; and *Neue Denkwürdigkeiten*, 1ster Band, 2ter Bogenzahl. p. 28, Göttingen, 1799.

† *Neue Denkwürdigkeiten*, § 119, p. 282.

himself at the close of his active life concerning turning in cases of pelvic deformity, in the following decided manner:—

"Ne itaque, quin necesse sit, infantem convertas; tum vero minime, ubi non sat justa pelvis spatia habet. Vesano certe consilio capite prævio, at prægrandi, vel quod ad idem redit, pelvi angusta atque ex hac molesto nixu, versio patrat. Tale facinus infanti ac matri numquam non exitio est."*

As the medical literature of Germany is probably not so readily accessible to all members of the profession as that of our own country and of France, I will just add, that the doctrine at present taught there with reference to this point is,† that turning may be employed with advantage in cases where there exists a moderate degree of pelvic deformity, coupled with not very active pains (which have proved inadequate to drive the head through the pelvic brim), and a dilated state of the os uteri. The younger Oslander has most fully considered this practice, and the objections that have been raised to it, and recommends‡ it as more generally applicable than the majority of his countrymen are disposed to admit, since he is inclined to practice it in many cases as a substitute, not merely for the forceps, but, after they have been unsuccessfully tried, as a means of avoiding the use of the perforator. He denies the great danger or difficulty of pushing back the head, and turning the child, after the forceps have been ineffectually applied, and states that he has under such circumstances turned with facility. He denies that the difficulty in extracting the head when it comes last is as great as when it presents, and appeals to general experience in proof of this statement. "The reason why the child which could not be brought into the world while its vertex presented can be delivered after it has been turned, ap-

pears to be, that when the head presents, its broader part has to be drawn through a narrow passage without its being held fast, except at its sides; while, on the other hand, after turning it offers the under part of the face and the neck like the narrow end of a wedge, and thus its smaller part, coming first, can be firmly held on either side by the forceps, and, if need be, can have additional force applied to move it, by drawing at the lower jaw, and by pressure on the back of the neck and shoulders."*

"That by this proceeding the life of the child may be destroyed is fully admitted, but at least," says he, "it gives a chance which embryotomy at once destroys."

In addition to those cases in which turning may be resorted to after the application of the forceps, he recommends it as a proceeding to be adopted from the first under the same circumstances as those in which others of his countrymen adopt it, though he does not agree with them in admitting the fruitlessness of long continued uterine efforts as contra-indicating its employment. He moreover advises it in cases where previous tedious labours have issued, after much suffering, in the birth of dead children, and considers that under any of these circumstances the existence of any irregular position of the head renders this proceeding the more imperative.

In the foregoing sketch my object has been, avoiding all occasion of controversy, to acquit myself faithfully of the duties of a historian. My reason for undertaking this office was, that not a little of the asperity which has, unfortunately, entered into recent debates in this country concerning the propriety of turning the child in cases of pelvic deformity, seemed to me to be due to the fact of the proceeding having been regarded, both by its advocates and its opponents, as or almost altogether novel, instead of being one which has engaged the attention of some of the most competent observers and best practitioners ever since the invention of the forceps, and has employed their pens, either in setting forth its advantages, or in exposing its evils.

* De Obstetricia Naturali, p. 223, 8vo. Vienna, 1830.

† Siebold, Lehrbuch der Geburtshülfe, § 518, S. 414, 8vo. Berlin, 1841; Killan, Operationslehre, 2te Aufl. Band. i. S. 326, Bonn, 1849; Wilde, Das weibliche Gebärungsvermögen, S. 250, 258, 8vo. Berlin, 1831. The size which the pelvis ought to have to justify this operation is not estimated alike by all writers. Oslander and Siebold take three inches as the minimum; Killan three and a quarter to three and a half.

THE DETECTION OF SEMINAL FLUID IN THE URINE IN CASES OF MASTURBATION.

MICROSCOPICAL APPEARANCE OF THE ZOOSPERMS.

By THOMAS INMAN, M.D.

A FEW days since I received from Dr. Brett a specimen of urine for microscopical examination. It was lightish in colour, somewhat turbid, of sp. gr. 1018, did not answer to the test for sugar. It had a somewhat peculiar smell; and, after keeping a few days, was loaded by a vegetable growth like the torulæ of diabetic urine. It showed little tendency to putrefaction,—so little, that some which is now twelve days old, and has been kept in a warm room, exposed frequently to the atmosphere, smells perfectly natural, and is without any ammoniacal odour. Another specimen has been kept in an open wine-glass for about a week, and is still sweet.

On making a microscopic examination of the fluid, I found that it contained, in addition to the torulæ, a number of large fragments of epithelium adhering together, and evidently large exfoliations of very large tubes. There was also an immense number of organic granules, which I at first considered might be pus.

The general characters of the fluid not being those of a purulent urine, I made a closer investigation, and at last found a number of spermatozoa. The urine was spermatic! and the case was most probably one of extreme masturbation.

This was not, however, the most interesting discovery I made; for I was enabled most unequivocally to see the relation between the so-called animalcules and the seminal granules. Before detailing this I may mention that I have long been dissatisfied with the figures given of the zoosperms, inasmuch as they never show any caudal appendage. Now I have found, in an immense number of instances, that there is a peculiar formation at the base of the tail. This is so common that I consider it the exception when the animalcules are deficient of it. It consists of a delicate transparent membraniform substance, which may readily be detected by a good $\frac{1}{4}$ inch and a low light. It may be thus figured:—

a solid body; b sac; c caudal appendage.

This appearance could only be accounted for in my own mind by the supposition that each zoosperm was developed in a cell, the tail protruding like a cilium, until the emission took place, when all the zoosperms were torn from their attachments, the other contents of the cell going to swell the amount of the secretion discharged, and that the granules were probably immature cells in which the zoosperms were undeveloped. This idea of the cell origin of the animalcule received its strongest confirmation from the fact that the appearance of No. 1 was the most common,—when it was evident that a fragment of *something* or other was carried away; and that *something* could only be a continuous membrane or a cell: everything went to disprove the probability of the former.

I was then diligently on the look-out for granules in the transition state; but my search was unsuccessful until I examined the above-mentioned specimens. I found in one of them a *granule containing a zoosperm*, of which the following is a sketch:—

It rolled over during the investigation, so that I could convince myself that the zoosperm was not simply an adherent one. Another granule was in a transition state, neither the tail nor the head of the zoosperm being fully formed: thus—

The size of these granules was about ~~over~~ of an inch.

I have been able to verify these observations on a subsequent specimen of spermatic urine from another source, and have now seen the appearance described in at least four separate cases.

I find, on reference to Todd's *Cyclopædia of Anatomy and Physiology*, that two observers have noticed analogous phenomena in the spermatic secretions of the dog and of the rabbit, and that Dujardin and Kölliker have noticed the caudal appendage. I have not seen the drawings of the former, and therefore cannot say whether we refer precisely to the same things. I believe no observer has yet noticed them in the human semen. The authors of the article consider that the appendage may be due to matters accidentally deposited by the urine, in which fluid the phenomena are usually investigated. This can scarcely be, as they are to be found equally in that fluid when freshly passed. The fact appears to be, that the spermatozoa can never be examined with so much satisfaction as when they are expelled with the contents of the bladder. After an emission a certain quantity of semen remains in the urethra. This is exposed to little violence, as it is not so readily expelled as the first quantity evacuated. This residuum is washed out by a stream of fluid, and the animalcules are never subjected to anything likely to destroy their character up to the time of their being placed in the field of the microscope.

Liverpool, Nov. 1850.

A CASE OF
PUERPERAL UTERINE PHLEBITIS,
WITH REMARKS.

By W. B. KESTIVEN, M.R.C.S.

Much has been written on the subject of puerperal fevers; the following case is intended as a contribution to its history. It is one only of the facts which constitute that history.

Mrs. A—, over thirty years of age, a native of New York, had accompanied her husband to England shortly after her marriage, and was pregnant with her first child; her health had been good throughout the period of gestation, and although having a pale and exsanguine aspect she stated that she had never before during her life required medical advice, that she had never before spoken professionally to a medical man. She was a well-made woman, and presented an ample pelvis: everything, therefore, promised a fair labour, except the fact of her having passed more than thirty years—how many more than thirty I could not learn—in the virgin state. I felt unusual confidence in endeavouring to dispel the ordinary despondency of pregnant women approaching the time of delivery, which in the present instance had obtained an unusual hold upon the patient.

Labour commenced on the 11th March, 1850, at eleven o'clock in the forenoon, and it was found that we had to deal with rigidity of the os uteri to begin with, and fair promise of a similar condition of the external organ afterwards. However, by dint of patience and other means, the dilatation of the os uteri was got completed by eleven of the forenoon on the 14th. The head having passed into the vagina remained just within the outlet, where it was detained, as had been found by the unyielding rigidity of the external parts. At eight o'clock in the evening she was seen by Dr. Robert Lee, who fully concurred in the proposal that the child should be removed by operative interference. The pains, although strong and regular, were clearly incompetent to the expulsion of the child, except at the expense of the soft parts.

The forceps were applied experimen-

tally merely; their use confirmed the suspicion that the life of the child must be sacrificed. Craniotomy was forthwith practised, the labour finally terminating at half past ten o'clock of the same evening. The placenta was easily and entirely cast off.

The patient went on favourably until the 22nd of March, with the exception (scarcely noticed by herself) that during this time she had not slept soundly. Her nights were rather restless, and disturbed by dreams. My fears were excited by this circumstance, but the closest watching detected no other bad symptom until the 22nd, the sixth day: when, while I was standing by her bedside, she had a severe and long-continued rigor. This returned also less severely on the night of the 22nd—23rd, but no other bad symptom had yet shown itself.

On the 23rd, the patient acknowledged to no pain, but stated that she had an unpleasant feeling of heaviness of the head and confusion of ideas. The skin had become hot and dry, the bowels confined, the tongue furred; the pulse had risen to 140, and was small. Castor oil, and a mixture of Liq. Ammon. Acet., with Dover's powder, were prescribed.

24th.—Passed a restless night, at times delirious; has the same sense of confusion; the countenance has assumed a peculiarly sharp and anxious look. Bowels freely purged; the skin moist and less hot; the tongue furred, the papillæ at its apex red and enlarged; the pulse 136, small; has no pain or tenderness in the abdomen or hypogastrium.

Emp. Canth. Nachæ. Calomel and Dover's powder. Towards evening of this day the pulse fell to 100, and was soft, the skin moist and cooler.

25th.—The symptoms continued much the same, with these important exceptions, that on this day she first acknowledged pain and tenderness in the hypogastric region, and the lochial discharge had considerably decreased; at the same time that she expressed herself "much clearer in the head." Painful forcing sensations in the vagina and rectum were felt, and the hypogastrium had become exceedingly sensitive to pressure. No pain in the groins or thighs. Calomel, Opium, and Leeches.

26th.—Has slept at short intervals. mind clear. The pain had increased, and --

man, which was tympanitic. The countenance flushed and more anxious; no headache; the tongue thickly covered with a brown fur; great thirst; the skin pungently hot; pulse 160, feeble; bowels confined; urine scanty and high coloured; lochia entirely suppressed.

The patient was seen again this day by Dr. Robert Lee. Calomel and opium continued; leeches repeated.

27th.—The leech bites have bled freely; considerably difficulty was experienced in arresting their bleeding. The pulse during the night was so frequent and feeble that it could scarcely be felt at times. The heart's action was so much depressed that it was necessary to administer brandy every two hours, for six hours, when the pulse fell to 140, and became fuller. The bowels acted. The tongue had lost its brown fur, and presented a clean dry glazy aspect along the middle, with a white moist fur at the sides. The pain and tenderness of the hypogastrium remained much the same, but was rather less extensive over the abdomen. Mind quite clear, no headache. Countenance less anxious. The right forearm had become swollen and painful; the calf of the right leg also was tender to the touch. In the afternoon, redness, swelling, and tenderness over the patella of the left leg appeared. Pulse 160, feeble. Towards evening the pain and tenderness of the abdomen had nearly subsided. Diarrhœa occurred, and a painful sense of constriction about the epigastrium. Vomiting also occurred once.

Seen again by Dr. Lee. To continue brandy (3ij.) every four hours. Bark and ammonia. Fomentations constantly to the painful parts of the limbs.

28th.—It was requisite to administer starch and opium enemata frequently during the night. The pain in the leg and arm prevented her from sleeping much; started a good deal when dozing. The pulse varied during this day as to number and strength, sometimes being too rapid and feeble to be felt, at others falling to 140, with some appearance of power. The skin bathed in profuse perspiration. Diarrhœa persistent. The tongue somewhat moister, and quite clean. Quantity of stimulant decreased a little.

29th.—Had passed a quiet night. Bowels had not acted. Pulse 120, with a

clean and moist; skin cool and moist; is rather drowsy, but easily roused. Passed several stools involuntarily in the course of the day.

30th.—Passed a quiet night; some muttering and subsultus during sleep. Pulse 120, feeble; tongue clean; aphthæ appearing in the mouth and fauces; diarrhoea recurred; skin perspiring. Complained of severe pain in the left shoulder on this day. Increase stimulants, bark, &c.

April 1st.—Much the same in every respect. The abscess in the right arm was opened by a small puncture; it freely discharged good pus.

On several following days all the symptoms had improved considerably. The pulse had fallen occasionally to 104, and was fuller; the tongue had become moist and clean, the bowels acting more naturally, the appetite beginning to return, sleep more refreshing, some strength returning, so that she was able to sit up for an hour or two daily. The shoulder continued painful on touch or movement, but exhibited no external signs of inflammation.

Against these apparent signs of recovery, however, we had to set off her æmemic aspect, the fluctuations of the pulse from 104 to 120, and, after the 7th of April, an evening accession of hectic. On the 25th the right calf became more swollen and painful. This continued to increase, and on the 28th a deep narrow puncture let out about six ounces of pus, affording great relief. The shoulder also had become swollen. On the morning of the 29th the puncture made in the calf had closed; the cavity again filled, causing much pain; a director reopened the abscess, and liberated a similar quantity of pus, at first slightly streaked with blood. In the afternoon the sac of the abscess had again filled: it was very tense, hard, and painful: the introduction of a director was followed only by a flow of serum and blood in the first place; afterwards a small quantity of pus oozed forth. The orifice was enlarged, with the same result; severe rigors followed, and a feeble countess pulse. The suspicion that the sac of the abscess had become filled with coagulated blood was confirmed by the subsequent discharge of blood and conglua into the dressings. This sanguineous discharge never ceased from this period to the time of her death. Dr. Lee, who had throughout seen the pa-

tient occasionally, advised the application of ice to the leg, and a continuation of the Tinct. Ferri Muri, which she had been taking from the first occurrence of hæmorrhage. Petechial spots now appeared on various parts of the body and extremities. On the 30th April an expectoration of blood from the fauces took place. On the following day the patient became drowsy, and continued so until coma ensued on the 4th May. She had gradually sunk from the 2d, on which day blood was also passed with involuntary stools. Death ended the case on the 6th May.

Post-mortem examination, 24 hours after death.—The general blanched aspect of the body was that of death from loss of blood. Petechial spots in various parts.

Thorax.—The pleural sacs contained each about twelve ounces of clear serum. On the right side old pleuritic adhesions existed. Petechial spots were perceived under the pleura covering the lungs. The pericardium enclosed about four ounces of sanguineous serum. The surface of the heart presented numerous small petechial spots. The lungs presented extensive inter-vesicular emphysema; œdema existed posteriorly to a considerable extent. Corresponding to a puckering of the surface of the left lung was found a mass of soft, calcareous, and tubercular matter, about the size of a horse-bean. In the right lung a small pea-shaped substance, hard as stone, and of a black colour, was found enclosed in a cyst.

The heart was of a normal size, but its muscular structure was soft and flabby: its inner lining was studded with extravasations of blood: its cavities contained but very few coagula, and those soft and loose.

In the abdominal cavity the only morbid appearances were numerous ecchymoses under the serous membrane of the intestines and parietes.

The uterus had recovered its usual size in the unimpregnated state. *It exhibited no trace of disease of any kind. The ovaries were equally healthy.* These organs, as well as every other tissue and structure of the body, were pale and bloodless.

The large veins of the pelvis and thigh were examined, but showed no disease.

The cavity of the abscess in the calf of the right leg extended from below the knee-joint nearly to the ankle, and

was filled with blood, coagula, and pus: its lining membrane was of a deep red colour. No abrasion of the surface or open vessel could be discovered.

The bursa patellæ of the left knee was filled with pus. The shoulder-joint contained from four to six ounces of blood-discoloured pus: the cavity was lined with lymph, except on the external surface of the head of the humerus, where the bone was denuded.

REMARKS.—The case which is here related possesses many interesting features. It is probable, however, that other circumstances of a non-medical character may have invested this case with undue importance in the eyes of the writer.* The following reflections may nevertheless be offered on several points in the history.

In the first place, looking at the results of the post-mortem examination, it might be doubted whether this was really a case of inflammation of the uterine veins. No trace whatever of inflammation, or its termination, it has been seen, were discoverable in the uterus or its appendages. This was probably explicable on the supposition either that coagula or fibrin may have existed in some veins that were not examined; or that the poison, whether pus or morbid secretion, may, in the course of the disease, have become completely eliminated from the uterine or pelvic veins; or, that they were arrested only in those parts which, in the course of the case, showed signs of local disease—*e. g.*, the leg, arm, and shoulder; while, from the irritation thereby induced, the system became so deranged that the morbid condition of the blood which ultimately led to the immediate cause of death was produced.

It is true that the essential characteristic of pus in the blood—*viz.*, coagulation—was wanting, yet the symptoms throughout the progress of the case

were precisely those met with in cases where the post-mortem evidence of inflammations of the veins are obvious and sufficient. Hence it is probable that the pus or morbid secretions had been transmitted throughout the entire circulation. That such a result is possible is confirmed by the experiments of Mr. Henry Lee, related in his Jacksonian Prize Essay on Inflammation of the Veins, recently published, besides the facts of the case now before us, and the history of many analogous cases of the impregnation of the blood with diseased matter—*e. g.*, glanders, &c. &c.

Looking to the symptoms, it may be observed that in the progress of this case the first effects of a circulation of blood in a diseased state was felt in the cerebral functions. It is not possible in the present instance to fix precisely upon a period at which the disease may have been said to have commenced. No symptoms were distinctly perceived until the sixth day after delivery; and these, although we could not but fear their real nature, were not shown to proceed from uterine inflammation until three days later, when the obscure head symptoms greatly abated, concurrently with the manifestation of active uterine disease. These suddenly lighted up with energy on the 25th and 26th, and then, with the usual character of purulent infection of the blood, depression of the whole system speedily ensued. The entire course of the disease exhibited all the features of uterine phlebitis as described by Dr. Robert Lee and other authorities.

The long continuance of the case (from about the 23rd of March to the 22th of April), and the progressive abatement of many of the worst symptoms under incessant watching, and supporting with stimulants and the strongest diet, encouraged expectations of a favourable termination. These, however, were destined to be disappointed: the blood was too much vitiated to admit of healthy reparative processes; the functions of assimilation and sanguification were necessarily impaired; and the consequences were seen in the still further exhaustion produced by purpura hæmorrhagica, against which her enfeebled frame struggled in vain.

The opinions of various authors on the nature of such inflammation as we had here to deal with might be quoted; but, as has justly been remarked by

* The words wherein to express some of these circumstances may be borrowed from Dr. Churchill's "Historical Sketch of the Epidemics of Puerperal Fever:"—"The course of a favourable parturition suddenly interrupted, and, without any appreciable cause, exchanged for symptoms which excite the utmost alarm in the physician—the anxiety and anguish of those so lately rejoicing—the blighting of the sweetest hopes in life; and, finally, the rupture of its dearest ties, and the melancholy desolation of a home so lately the abode of happiness." Besides these considerations, the patient was a lady of great literary acquirements and brilliant talents.

Professor Paget, in his valuable lectures on Inflammation, when speaking of morbid conditions of the blood as one of the circumstances of inflammation,—“I fear that the nature of this disturbance cannot yet be chemically expressed, and that the facts which chemistry has discerned in the condition of the blood in inflammations cannot yet be safely applied in explanation of the local process.” The case now before us supplied forcible illustration of the correctness of this statement. It would, for instance, be impossible to account for the cessation of inflammatory action in the veins of the uterus, the transmission of the poison by the general circulation, and the determination of local inflammation to special parts, as the joints, and among the muscles, rather than in the lungs or any other viscus.

One or two points of treatment presented subjects of deliberation during this case, and, practically, it may be useful to allude to them.

1st. With regard to the time and extent of depletion: it is doubtful, if venesection had been practised at the outset, or when the rigors occurred, whether the subsequent symptoms might not have been arrested. The answer must be in the negative, depression being one of the worst results of the circulation of contaminated blood.

2d. Whether any other plan than that of simply supporting the system, with a hope that in time the poison in the blood might be eliminated? There are no medicines which, under such prostration, can be supposed to offer an especial prospect of such elimination within the period that fatal injury must have been inflicted, or before the natural powers of restoration could have been re-established.

3rdly. With regard to the local treatment of the inflammations and suppurations in the joints or elsewhere: how soon should abscesses be opened in such cases? In answer to this inquiry, Sir Benjamin Brodie's advice* applies to this as to other collections of pus, under certain restrictions:—

“It is not generally advisable to open an abscess while there is any considerable mass of substance between it and the skin, on account of the hæmorrhage which may take place into its

cavity, and, by putrefaction, produces typhus and fatal results.”

In the local collections of pus following on uterine phlebitis, and not enclosed in the cavities of joints, it is desirable to let out the matter, as early as distinct fluctuation is perceived, by a small deep puncture. If the pus be allowed to find its own way to the surface, further detriment accrues to the constitution from the irritation which is caused by its further burrowing among adjacent structures. When, however, there is evidence that the sac of a joint contains pus, as was the case in the shoulder and the bursa of the patella in the example before us, it is, as the same high authority remarks, not advisable to open it until the skin over it has become very thin. Neither the shoulder joint nor the bursa were opened, for the reason that in the former fluctuation was distinct only within a short time of death; and that in the latter the swelling was slight, and the pain inconsiderable; under which circumstances it was not deemed justifiable to incur the risk of additionally inflaming its sac, as was probable if it were laid open.

Lastly, this case serves to throw some light upon one very important and disputed point in the history of puerperal fevers—i. e. the question of infection. The history which is contained in Dr. Collins's invaluable practical treatise; the cases related by Dr. Robert Lee in his lectures, and in his work on Puerperal Diseases; the history of the Epidemics of Puerperal Fever, by Dr. Churchill;* the account given by Dr. Routh of the occurrences connected with puerperal fever in the Vienna Hospitals; the lectures of Dr. Murphy;† the facts which must be familiar to every one engaged in obstetric practice;—all prove the possibility of the disease being communicable.

“I fear we must conclude,” observes Dr. Churchill, after quoting the evidence of Drs. Lee, Robertson, Copland, Ramsbotham, Blundell, Davies, &c. &c., “however reluctantly, in favour, not merely of the contagiousness of puerperal fever, but of the possibility of its contagion being carried by an intermediate party.”

* *Essays on Puerperal Fever and other Diseases of Women*, Published by the Sydenham Society.

† See the last volume of the *Med. Gaz.*

The present instance may either be regarded as one of the epidemic prevalence of the disease, or of the coincidence of several sporadic cases. At the time of its occurrence no other case had been known in my neighbourhood for several years: none have occurred since, although I attended several other ladies during its progress. I did so under the conviction that it was a sporadic case, since, although Dr. Lee had been called in consultation to several cases around London at the same time, yet no case of the kind had occurred to him in his own private practice. In the next case that I attended severe rigors occurred on the third day; but no further ill effects ensued.

It may therefore be regarded as a proof that the disease may be sporadic as well as epidemic or contagious, and it also furnishes an argument why a medical man should not discontinue obstetric practice on the happening of a single case of puerperal fever, since it obviously incurs no obligation to abandon his engagements. Other cases occurring, however, in the practice of the same individual, the predicament is entirely changed, and a man's ethical principles must take the precedence of his professional requirements.

Upper Holloway, Nov. 1, 1850.

EXPERIMENTAL RESEARCHES ON THE THEORY OF A HEPATICO-RENAL CIRCULATION, AND ON ANIMAL HEAT. BY M. BERNARD.

M. BERNARD having administered prussiate of potash to a dog, and ascertained the existence of this salt in the urine within ten minutes, killed the animal, and examined the blood separately from the renal artery and vein. The latter contained a large proportion of prussiate of potash, the artery none at all. This was the reverse of what M. Bernard had expected. It happened that the salt had been administered on a full stomach. Surprised at the result, M. Bernard repeated the experiment many times, and found that, when given during the process of digestion, the prussiate was always found in the vein; if given on an empty stomach, it was uniformly discovered in the artery.

In tracing the course of the prussiate from the stomach to the kidneys, it was constantly found in the blood that left the stomach and intestines—i. e. in the portal system; while it was never met with in the general venous circulation. It is obvious,

therefore, that during digestion a circulation obtains different to that which exists while fasting.

This circumstance, M. Bernard states, explains the discrepancies met with in the results of investigations on the presence of various salts in the urine. It gives a clue, also, to many other obscure phenomena. It is known that the absorption of poisons is more active during fasting, and under loss of blood; and that their absorption is retarded by the injection of water into the veins: the fact has been explained on the greater or less degree of tension of the blood-vessels. It has been noticed, also, that certain poisons are harmless to some animals, and noxious to others. For instance, the rabbit is not poisoned by atropine, while the dog is so: this is accounted for, according to M. Bernard, by the circumstance that the rabbit, although it may not recently have partaken of food, has constantly alimentary matter in its intestines. The atropine absorbed by the portal vein traverses the liver, and, passing by the vena cava to the kidneys, is excreted in the urine; not having passed by the general circulation, except in very minute quantities.

M. Bernard has performed a series of experiments on dogs and rabbits, the results of which support his theory of a special circulation that relieves over-fullness of the vascular system. These researches, the author observes, show also that the endemic method of applying medicines will often be more certain than their administration by the digestive organs.

Is the hepatic circulation one of the sources of animal heat?

M. Bernard observes that the connection between the renal and hepatic circulations with that of the intermediate vena cava, is the physiological condition in the fœtus; M. Bernard states that in after-life the blood passing from the liver during active digestion is at least one degree higher than that of the blood as it enters the same organ; and that the injection of solids and fluids reduces the temperature of the blood in the portal vein. The temperature of animals is reduced by three or four days abstinence. The insufficiency of the observations made on the increase of temperature in the lungs, together with a consideration of the great extent to which secretion takes place in the liver, and the activity of its circulation during digestion, are, in Dr. Bernard's opinion, sufficient reasons for attributing to the liver a principal share in the production of animal heat.

MEDICAL GAZETTE.

FRIDAY, NOVEMBER 29, 1850.

In our last number we made some general remarks on the evidence adduced before the Parliamentary Committee on Prison Discipline, in reference to the supposed injurious effects produced on body and mind by the adoption of what is termed the **SEPARATE SYSTEM**. We have now to consider those facts contained in the Report which tend to show the error of the commonly received opinion, and to prove, that whether as regards health or the reformation of the individual, it is not, when fairly carried out, attended with that danger with which it has been hitherto associated.

We shall now proceed to lay before our readers the evidence which contains the facts to which we allude. And first, that of one of the most competent witnesses, Dr. G. Owen Rees, who has held the office of Superintending Physician of the Pentonville Prison, since its opening. Dr. Rees has watched the "experiment" from the first, and has arrived at the conclusion that the system is innocuous. We quote from his evidence:—

Q "Will you be good enough to state to the Committee how long a period you think a prisoner in Pentonville may be kept with safety to his mind and body, under the separate system of confinement?"

A "I think *eighteen months* is a very fair period."

Q "Do the prisoners in general improve towards the end of the year for which they are subjected to the separate system?"

A "It has appeared so to me."

Q "They are better in mind and no worse in body?"

A "I think so."

Q "You used the expression in the first part of your evidence, that you thought eighteen months was a very

fair period for the separate system; what did you mean by that expression?"

A "I think it is a period that might be adopted in general, without much injury to the prisoners."

Q "Former witnesses have almost unanimously told us that twelve months is, in their opinion, a better period for which the separate system, as a maximum period, should be applied?"

A "I speak from my experience at Pentonville, where the system of separate confinement has been applied in a modified manner, different from the way in which it has been applied in other prisons; so that I should say the system in other prisons has not been so good as the system pursued at Pentonville?"

Q "And at Pentonville you are not afraid of eighteen months separate confinement?"

A "No; as regards the effects upon the minds of prisoners, of separate confinement, which is a very important point, I should observe, *that the cases of insanity or delusion, which have occurred have generally occurred at early periods of separate confinement, and not at advanced periods.*"

Q "Do you think that the power of memory is equally great, after a period of separate confinement, as it was before?"

A "I have visited a number of men with a view to see whether the memory fails, that point having been very frequently insisted upon; and from attentive observation I can state, that in my opinion, *eighteen months separate confinement does not impair the memory.*"

Q "Have you heard of any prisoners who have been confined for a long period being subject to fits upon their discharge?"

A "Yes; I have seen men in fits. *Men have suffered from fits since the period was shortened.*"

Dr. Rees also states in the eighth Report of the Commissioners of Pentonville Prison, that in addition to four attempts at suicide during the year 1849, "there is an irritability observable, which I have never before noticed among men confined in Pentonville"

How far this irritability may be connected with the alterations lately made

in the system, and how far it is related to the increase of insanity under the short periods of imprisonment, admits of doubt. As a question of fact it still remains to be determined.

We may here notice those anomalous convulsive attacks, referred to by Dr. Rees, which have been observed in the prisoners on their embarkation for the penal settlements.

"Mr. Hampton states, that the sudden change from great seclusion to the bustle of a crowded convict-ship, produced a number of cases of convulsions, attended in some cases with nausea and vomiting; in others simulating hysteria; and in all being of a most anomalous character."

Mr. Hampton subsequently informed the Commissioners of the prison that these hysterical convulsions were propagated among the men by imitation. This we know to be common in the cases of females. The fits entirely ceased on the third day after leaving England.

These convulsive attacks are difficult of explanation. The cause to which they were assigned by Mr. Hampton is clearly insufficient, inasmuch as the measures adopted by the Commissioners for their prevention, on the assumption that they resulted from the causes pointed out by him, have not proved effectual for their prevention. It was given in evidence, that previously to recent embarkations the prisoners had been associated in a most unrestrained manner, to the number of 100 and 200, chopping wood, and making every conceivable noise that could be made, to inure them to what they would experience on board ship, and yet that not a single fit occurred while they were thus associated. They occurred, however, on embarkation, but not when the prisoners were put on board the hulks in the Thames. These fits have been noticed also in greater proportion among prisoners who have undergone the short

period of confinement than among those of the longer periods. A very singular fact is stated in reference to the convulsive attacks. The prisoners who embarked in one vessel experienced no fits, and the majority of these had been in confinement for periods ranging from eighteen to twenty-three months, and, being under the most rigid separate discipline, they *had not been associated previously to embarkation.*

Putting all these circumstances together, the only explanation that occurs to us is that the fits must be regarded as the consequence of a peculiar condition of the nervous system, resulting from the combined effect of the sudden change from separate imprisonment to complete and free association amidst the bustle of a convict ship, together with the effect on the mind produced by the certainty of banishment from all the ties of home and country.

The conclusions of Dr. G. O. Rees with regard to the effects of separate imprisonment, are confirmed by the admissions of Mr. Bradley, surgeon of Pentonville Prison.

This witness was asked:—

Q. "What is your opinion of the effect of the separate system upon the bodily health of the prisoners?"

A. "I think that towards the end of the twelvemonth the bodily health begins to be affected; the prisoners become pale, and I think the seeds of consumption are in many cases developed."

In answer to other questions, Mr. Bradley states:—

"I do not know that the separate system itself produces consumption during the first twelvemonth."

"I believe that the cases of consumption between the twelfth and eighteenth month are double the number of those that occur during either of the preceding six months."

Q. "What is your opinion of the effect of the separate system upon the mind?"

A. "During the last seven years there have been many cases of mental

disease, the greater number of which have occurred during the first six months."

"There are two periods at which the pressure seems to be greatest: the first period is from six weeks to two months after admission, and the latter period is towards the end of the first twelve-month."

In reference to this statement, we may observe that no facts are adduced in its support.

Q. "Do you think it possible that, even where actual insanity did not arise, the mental powers might be impaired and the memory affected without your detecting it in the prisoner?"

A. "Certainly." "I think some cases have occurred of the kind you speak of, where the intellect has been rendered obtuse, and the man has become stupid at the end of the first six months. When I speak of the cases of insanity, they are a small minority." (!)

Q. "What is the maximum time you would recommend for the infliction of the separate system, looking to the health of both body and mind?"

A. "Twelve months."

Q. "Not more than that?"

A. "No."

Q. "Do you find cases where the separate confinement is beneficial both to the body and mind of the prisoner?"

A. "Undoubtedly."

Q. "Inducing habits of repose and general tranquillity of mind?"

A. "Yes."

Q. "Are those cases the majority?"

A. "They are."

Q. "There is no other bodily disease (besides insanity and consumption) to which the separate confinement predisposes the prisoners?"

A. "Heart disease has been said to have occurred among a great many of the men in separate confinement. I have examined a large number of men, with a view to discover whether heart disease existed or not, and I cannot say that I found any cases of diseases of the heart that could be fairly attributed to the system; but of cases of functional derangement of the heart and palpitation, accompanied with pallor of the face, there have been a great many."

Q. "On the whole, judging from

your experience, supposing the separate system to be strictly limited in time, and carefully guarded by watching the health of the individual inmates of the gaol, I understand you to say that you think it rather tends to improve than to injure their health?"

A. "I think so."

Q. "But if not carefully guarded, or if carried too far, it is full of danger?"

A. "Yes."

Q. "Do you consider the mere fact of a prisoner being kept by himself is likely to induce consumption, where no tendency to it existed in the constitution before?"

A. "I am inclined to think that there is an amount of mental depression produced by separation which does tend to develop tubercular disease; but on the other hand, there are many, I believe, who come in with consumptive symptoms, and who are cured by a residence in the prison. The altered circumstances, the good diet, and the uniform temperature of the cells, in many cases have effected a cure."

The next evidence which we shall quote, though not strictly professional, is perhaps the more striking on that account: it is also the most decided and the most explicit with reference to the modifying influence of time in ameliorating the supposed evil consequences of the separate system upon *mental health*. We desire particularly to draw our readers' attention to the *facts* and statistics stated by the Rev. J. F. Burt, Assistant-Chaplain to the Pentonville Prison.

Q. "Are you not apprehensive of any danger to the prisoners if that system were strictly carried out for a long period of time?"

A. "None whatever; not greater than in other prisons. I may perhaps answer that by fact, rather than by opinion: the number of mental cases has never been so numerous or so disastrous in any equal period as since the relaxation of the discipline."

"From the opening of Pentonville to the present date the total number of mental cases have been,—insanity, seventeen; and of these fifteen have occurred before the twelfth month, and two after: delusions, nineteen; of these

fifteen have occurred before the twelfth month, and four after. Putting both classes of cases together, the result is a total of thirty-six cases; before the twelfth month, thirty; beyond the twelfth month, six."

Mr. Burt proceeds, in answer to other questions:—

"The Pentonville Prison has been opened seven and a half years: I will distribute that time into two periods—one in which the prison has contained the greatest number of prisoners for terms not exceeding twelve months, the other those years in which it contained the greatest number for terms exceeding twelve months, to an average of seventeen or eighteen months, and in many cases running on to twenty-two and twenty-three months. The one period embraces four years, the other three and a half years. The mental statistics for those two periods are as follows:—During three and a half years of short imprisonments, daily average population about 440; cases of insanity, 14; delusion, 11; suicides, 3; total, 28. During four years of long imprisonments, daily average population 445; cases of insanity, 3; delusions, 8; suicides, none; total, 11. Thus the ratio of insanity to the daily population has been, during the period of short terms, nearly five-fold of what it was during the period of long terms, although one period is six months shorter than the other.

What is even more startling is the fact, that during the period of short terms, the ratio of insanity is much greater than in the period of long terms, to the aggregate number of prisoners coming within the walls of the prison, wholly irrespective of the difference of the time during which the same number of prisoners will have undergone the severe punishment of the cell. The average term of detention being in one period 18 months, and in the other 12; the aggregate number passing through the prison during equal periods

has been greater during the short term than during the long by about 50 per cent. The numbers are, for the period of short terms, about 2,444; for the period of long terms, 1,627; difference, 817. Against that increase of 817 upon an aggregate of 1,627 prisoners, we have an increase of mental affections from 11 to 32. Thus the ratio of increase in the aggregate number of prisoners is as from 1 to $1\frac{1}{2}$; the ratio of all mental affections, as from 1 to $2\frac{1}{2}$; of insanity alone, as from 1 to about 5."

We must reserve our further examination of the Report until next week.

Reviews.

An Inquiry into the Nature of the Simple Bodies of Chemistry. By DAVID LOW, F.R.S.E. 2d edition, enlarged, 8vo. pp. 344. London: Longmans.

SOME time has elapsed since we received this book; but, owing to accidental circumstances, we have not had an earlier opportunity of laying a notice of it before our readers. It is strictly an essay on the higher branches of philosophical chemistry, from the pen of a man well acquainted with the science, and aware of the difficulties with which its fundamental theories are beset.

Mr. Low professes to furnish reasons for believing that the bodies now called *simple*, or *elements*, by chemists, are really compounded, and that the elementary forms of matter may be reduced to a very small number. He argues that we must not assume substances to be elementary or simple "because we have been unable to overcome the affinities of their constituent parts, or to convert them into any other form of matter." Berzelius has objected to this view that it will be time enough to examine the question when any one of the so-called elements has been proved to be compound by analysis. Mr. Low dissents from this proposition, and quotes the example of Lavoisier who predicted that the alkalies would turn out to be oxides before the discovery of potassium, sodium, and other alkaligenous metals. If Davy had sat down with the conviction that potash

and soda were elementary substances, he would not have made those brilliant discoveries which have shed such lustre upon his name. Even in our own time, Berzelius has himself stoutly contended for, and supported by ingenious arguments, the view that the now recognised element, chlorine, was a compound of oxygen and muriatic acid. Hence the same latitude must be allowed to Mr. Low to question the stability of the present views of chemists, and to prove, if he can, by fact or reasoning, that they are erroneous.

There are numerous singular analogies among elementary bodies in respect to light, heat, and their chemical relations to each other, which lead to the inference that they may be modifications of one and the same form of elementary matter. Chlorine, bromine, and iodine, present us with an example of this relationship, or, as Mr. Low would term it, of an isodynamic character. The section on chlorine affords a good instance of Mr. Low's mode of reasoning out the compound constitution of elementary substances.

It is well known that Cyanogen C^2N is a compound; and yet, in most of its chemical relations, it acts like a simple or elementary gas. It is, according to Mr. Low, isodynamic with chlorine. Thus the combinations of the two with hydrogen, mercury, silver, and potassium, are perfectly analogous: there is a want of analogy, however, in their combinations with oxygen, and an entire failure of it in the remarkable isomerism of fulminic and cyanic acids of which chlorine presents no example.

From the admitted analogies Mr. Low argues that chlorine and cyanogen cannot be dissimilar in corpuseular constitution; that if one be compound, the other cannot be simple. He proceeds to contend that carbon and nitrogen most probably enter into the composition of chlorine. Again, chlorine presents certain resemblances to sulphur "in the suffocating odour distinctive of both substances, in their unfitness for respiration, combined with the power in certain cases of supporting combustion, in the blanching properties of their compounds, and in their many dynamic relations." (110.) Considering that these resemblances of properties establish a resemblance of corpuseular constitution, it is conceived by the author to be probable that sulphur is also a constituent

of chlorine; and if one atom of carbon be removed from cyanogen, and one atom of sulphur substituted, we shall then have, instead of $Cl = 36$, the following formula: $C. S. N. = 36$. "Or if we choose to regard cyanogen as a carburet of CN, chlorine must be a sulphuret of the same base."

This reasoning is very ingenious, but wholly speculative: it falls far short of that accuracy which we look for in chemistry, and without which the science would present a mass of confusion. The so-called resemblances of sulphur and chlorine would prove just as readily that chlorine entered into the composition of sulphur as that sulphur was a constituent of chlorine. The hydracid compounds have no resemblance whatever in their chemical properties or effects on the body. As to the blanching properties, they are wholly different in kind. The bleaching by sulphurous acid is a real and soluble combination of the acid with the colouring matter; the colour is not destroyed, but it may be readily restored by a more powerful acid or base. In bleaching by the aid of chlorine the colour is destroyed, and cannot be restored.

We might quote other instances of inconclusive reasoning from this book, but we consider this unnecessary. With much that is erroneous in speculation, it contains a large amount of profitable reading. It is, however, a work which can be safely read and fairly appreciated only by the advanced chemist.

The Principles of Surgery. By JAMES MILLER, F.R.C.S.E., Surgeon in Ordinary to the Queen for Scotland, Surgeon to His Royal Highness Prince Albert for Scotland, &c. &c. Second Edition. 8vo. pp. 803. Edinburgh: Black. London: Longman. 1850.

MR. MILLER's writings are well known to be among the best contributions to surgical science. The first edition of the work before us has been so well received by the profession, and is so well known to surgeons, that we have now only to bring the second edition under the notice of our readers. We observe that the form of the volume is changed to the octavo size, and that woodcut illustrations have been copiously introduced, by which its usefulness is enhanced. At the end

of each subject, references have been made to its literature, which will also be found serviceable to the student. A section is added on the surgical use of chloroform, in which this subject is treated in all points of view.

We strongly recommend this volume, as presenting in a condensed form the best-founded principles of surgery, as laid down by its most eminent professors, and known experimentally to the author as safe guides in practice.

Lunatic Asylum Reports. Edinburgh: 1849. Belfast: 1850. Devon: 1849-49-50.

THE numbers of patients admitted into these several asylums during the past years were:—

	Males.	Females.	Total.
Edinburgh	109	166	265
Belfast	55	57	112
Devon, 1848			139
" 1849			116
" 1850			111

The report of the Devon asylum does not distinguish the sexes of the patients admitted.

The discharged were as follows:—

	Males.	Females.	Total.
Edinburgh, cured	42	77	119
" uncured	20	35	65
" died	42	37	79
Belfast, cured	24	28	52
" uncured	11	10	21
" died	25	18	43
Devon, 1848, cured	17	16	33
" " uncured	0	3	3
" " died	9	10	19
" 1849, cured	15	27	42
" " uncured	3	1	4
" " died	16	19	35
" 1850, cured	20	32	52
" " uncured	0	5	5
" " died	17	13	30

The forms of disease have not varied much from what has been exhibited in former reports of these and other asylums, which we have fully noticed on recent occasions.

Dr. Skae, in stating that more cases than usual of *Puerperal Mania* had been admitted during the year, takes the opportunity of noticing that their occurrence cannot be attributed to the use of chloroform, which had not been administered in any of these cases.

The most frequent cause of the disease which we observe in these Reports was *intemperance*.

In all the Reports we observe the same judicious plan of moral control which leads to the patient being treated as if he were sane,—the same care and attention to the bodily health, the same principles of moral and religious training, seeking to draw the sufferer out of himself, and to engage his mind with healthy and agreeable occupations.

It is much to be desired that the Commissioners of Lunacy would point out the features of greatest importance in the history of insanity on which it is desirable to obtain information, and that they would enjoin their publication in the Annual Reports of Asylums; the present desultory, and, too often, unconnected manner of stating the results of the year, leads to no public or professional benefit, and suffers many valuable facts to be entirely lost to science.

We would also suggest that the common octavo form should be adopted for the publication of Reports, so that a yearly volume might thus be formed, by binding together these scattered contributions. A hint from the Commissioners, and a plan suggested by them, would be productive of much improvement.

The Annual Report of the Verral Spinal Hospital for the Treatment of Diseases and Distortions of the Spine, Contractions of the Limbs, Hip-joint Disease, and Paralysis. 1850.

FROM the statements of the medical officers, Mr. Hugman, Mr. Charles Verral (son of the founder), and Mr. Day, this charity seems to be the medium of much good. We trust that the present appeal will not pass unheeded: the funds of the institution need support. When we state that twenty-four in patients, besides numerous out-patients, receive the benefits of this charity annually with the outlay of only four hundred and nine pounds, it will be evident that the utmost economy is exercised. One hundred and thirty pounds cover the salaries of house-surgeon, matron, nurses, and servants! The house-surgeon must be virtually an honorary appointment under such an expenditure. A series of cases are added in illustration of the advantages of the prone position in the treatment of spinal disease.

DR. ADDISON, PRESIDENT.

Ovariectomy.

AFTER the reading of the papers published in our last number on the subject of *Ovariectomy*, some remarks were made by various members, of which we subjoin an abstract.

MR. CÆSAR HAWKINS dwelt upon the necessity of obtaining a full and complete history of all the cases of operation, whether only commenced or carried through, with a candid statement of the results. He stated that the operation had now been performed by ten surgeons attached to London hospitals, and not one of these gentlemen had performed the operation a second time. Recovery took place in one case only. He appealed to Dr. F. Bird and Mr. Walne, who had frequently performed this operation, to publish a full account of the results of their practice, for the information of their profession.

Dr. F. BIRD observed that he had communicated his cases to Dr. Lee, but he had declined giving the details, because he objected to the manner in which Dr. Lee's tables were arranged.

Dr. LEE said that the information furnished by Dr. F. Bird was so meagre that he could not, in justice to the completeness of the other cases in his table, add those of Dr. F. Bird to the document. He subsequently remarked that out of *thirty-seven* cases in which an unsuccessful attempt had been made to remove the tumor, *fourteen* of the patients had died. The exploration of these tumors was by no means a harmless proceeding.*

MR. B. PHILLIPS agreed with Mr. Hawkins in condemning the practice of publishing successful and withholding unsuccessful cases. He considered it to be a suppression of the truth which every honest man would condemn. As ovariectomy is an

operation not often performed in public hospitals, but in private houses, it is doubly incumbent on those who have the means to remove the veil which may conceal the results of these cases.

Dr. TILT observed that he had followed out the individual history of each case, and had classified them accordingly. This was the only way in which the cases could be made valuable in determining the risk of the operation. For instance, some of the cases of ovarian disease were of a very chronic character, whilst in others the disease was so acute as to resemble peritonitis in a mild form. Now it would be obvious that to class these two forms of cases together might lead us to a most erroneous conclusion. In the chronic form of the disease, attacking patients late in life, it was, he believed, unjustifiable to operate; but in some cases, where the disease was more acute, and it occurred between the ages of eighteen and thirty, it might be justifiable. Dr. Atlee, of Philadelphia, had operated in thirty-six of such cases: of these twelve died, and twenty-four recovered. Looking at the mortality in those cases where no operation was performed, and to the fact that life was very rarely prolonged beyond two or three years, it would at once be seen how important it was to arrive at right conclusions respecting the operation. The question, then, immediately suggested itself, as to which were the cases most favourable for operation. Upon this point we must remain in doubt, so long as fatal cases, and their histories, were withheld from publication.

MR. LAWRENCE said,—Mr. President, I did not attend the meeting of the Society to give information, for I have no experience of ovariectomy; I have not performed it, and unless my view of the matter should be essentially altered, I never shall; nor have I seen it performed. I came, sir, to listen and to learn, and my expectations of information have not been disappointed. I have heard things strange and new, at the same time instructive. From the interesting document presented to the society by Dr. Lee,—for which he deserves the best thanks of the profession, the public, and more especially of females labouring under abdominal enlargements,—it appears that in 37 out of 108 authenticated cases of operation collected by him, it was found, when the abdomen had been exposed, either that there was no diseased ovary, or one so circumstanced as not to admit of removal. We cannot help believing that this announcement, however unexpected and startling, represents ovariectomy in too favourable a light. Dr. Lee's list is imperfect, confessedly so; it contains only the cases of which he has

* In a letter since published on this subject Dr. F. Bird observes—"I have extirpated large ovarian tumors in *thirteen* cases, of which number *nine* were successful, four unsuccessful; in one case the tumor could not be extirpated, and the patient sank. In eighteen other cases I have made small incisions, as a means of diagnosis or relief, and in no case did a bad result ensue from such incisions; leaving a total of thirty-two cases in the treatment or investigation of which the abdominal cavity has been incised."

received authentic accounts. There is no reason for supposing that any successful operations have been omitted. We have generally, perhaps invariably, heard of them, as soon as the cicatrization of the wound had been completed. The same alacrity has not been observed in the communication of unsuccessful cases; and I am not aware that any one of the thirty-seven cases just alluded to has been published by the operator. We can hardly doubt, therefore, that if a correct list were drawn out of all the operations, the proportion of cases in which ovariectomy had been fatal would be increased, and that a considerable addition would be made to the thirty-seven instances, in which the perilous proceeding of exposing the cavity of the abdomen had been resorted to unnecessarily. Dr. Lee's list, however, as it now stands, is quite sufficient to make us doubt the propriety of admitting ovariectomy into the catalogue of recognised and approved surgical operations. We are still in the dark on one point, which ought to be ascertained before we can determine the true value of the proceeding; that is, its influence in prolonging life.

Our excellent colleague may probably have acquired information on this point, in prosecuting the researches of which he has now laid the result before the Society, and he could probably render them still more complete, by learning the subsequent history of the cases, in which the operation had been successful, by ascertaining the kind of health enjoyed, and the duration of life after recovery. The chances offered by the operation would be expressed by the average duration of life in those who have undergone it, if that can be ascertained, reduced in amount by a deduction, and that not inconsiderable, on account of those in whom the operation ends fatally, whether completed by removal of the ovary or not. The result thus obtained must be compared with the probable duration of life in those patients who receive such relief as can be afforded by the other resources of art. Many years ago I saw a female from the north of England who had undergone ovariectomy, as it was reported, successfully, not very long before the time of my seeing her, the operator being Mr. Lizars. It was performed when what was then called the major incision was in vogue—that is, a cut through the parietes from the ensiform cartilage to the pubes, such as we make to expose the abdomen for examination after death. There was a sound cicatrix on the person of this female, indicating that an incision of that description had been made. The pelvic region was occupied by a large solid mass of disease. The comparison I have now suggested must be made between

two sets of cases similar in their nature. Ovariectomy is not performed indiscriminately, but in selected instances. The cases chosen for operation are exactly those in which it is least necessary, the danger to life being remote, and the patients sometimes living for years with only an occasional interruption of health and comfort.

Mr. Lawrence, in common with the other speakers, commented on the statement of Dr. F. Bird, that he had adopted the exploratory incision in *forty or fifty* cases. It turns out, however, that Dr. Bird has really only adopted this plan in *eighteen cases*: hence it is not necessary to insert remarks which refer to a number now admitted to be erroneous. It is very evident from this discussion on the excellent paper brought forward by Dr. R. LEE, that the feeling of some of the ablest men in the profession is decidedly adverse to this operation. This feeling will find a strong hold in the minds of all members of the profession, until a full and complete history of every case, without any reservation of details, has been published. We have no doubt much good will accrue from this discussion. As the facts at present stand, all must admit, with Mr. Lawrence, that Dr. Lee's list of cases, as it now stands, "is quite sufficient to make us doubt the propriety of admitting ovariectomy into the catalogue of recognised and approved surgical operations."

MEDICAL SOCIETY OF LONDON.

Nov. 9, 1850.

DR. J. R. BENNETT, PRESIDENT.

On the Treatment of Ovarian Dropsy by the Production of an Artificial Oviduct.

MR. J. B. BROWN read a paper on this subject. The operation he now proposed he would designate but a modification of a previous one proposed by Mr. Bainbridge, of Liverpool, and to that gentleman he would accord the merit of having first seized upon the guiding principle—that of setting up adhesions between the sac and abdominal parietes, and leaving the sac to exhaust and destroy itself, by its discharge through an artificial opening. The operation consists in making an oblique lateral incision in the middle third of the oblique line, extending from the umbilicus to the anterior superior iliac spine, reaching at first to the peritonæum, then puncturing and emptying the cyst by a trocar and canula, and the peritonæum being reflected, to subsequently stitch the cyst to the aponeurotic tendon of the external oblique muscle; and this being done, to divide the

cyst between the line of the sutures; and, finally, in keeping up the communication between the interior of the cyst and the exterior, allowing the free and constant escape of all secretions produced within it. This operation of Mr. Brown differs from that practised by Mr. Bainbridge, in that the fistulous opening is formed in the side, and not in the middle line, whereby the discharge from the wound is facilitated, and the greatest comfort to the patient ensured. In illustration of the practicality and advantages of the operation, Mr. Brown proceeded to narrate the history of three cases in which he had carried it into practice.

In the first case, which was one of long standing, tapping had been performed several times. It afforded the patient so little relief on the last occasion, and her health was so rapidly giving way, that it was determined to perform the operation under discussion. The patient went on well for five days, but then became subject to fainting fits and much dyspnoea. Dr. Sibson considered that the patient suffered from disease of the heart. She died within a month of the operation. After death a considerable amount of visceral fluid was detected. The ovarian cyst was adherent all round the incision. It communicated at its posterior surface by an opening of some duration with a smaller cyst, and by this with several others. The contents of these cysts differed in their nature. In commenting on this case, Mr. Brown said, he regarded the fatal result to be mainly attributable to the amount of organic disease present, and that it did not militate against the value of the operation.

The second case was one in which tapping afforded so temporary a relief, that this operation was performed; her general health, however, and weakness, holding out but little hopes of success. The walls of the cyst and peritoneum were found adherent, and an apparently solid elastic tumor occupied the interior of the cyst. All went on well for the first fortnight; she then caught cold, and suffered considerably. This was overcome by remedies; but the discharge diminished, and this was found to arise from adhesion between the walls of the cyst and the tumor. The effect was the division of the cyst into two compartments, from one of which no fluid was evacuated. The evil was removed by breaking down the adhesion, and placing in the orifice a pledget of lint. The operation was performed in April. She went on well without any remarkable symptoms until July, when the large cyst in a putrescent state escaped through the orifice. At the end of August vomiting of a persistent character set in; she was seized

with paralysis of the left side, and died comatose. An autopsy being made, a cyst capable of holding an orange was found in the right ovary, communicating externally by a healthy fistulous canal. The wall of this cyst was soft and disorganised posteriorly, and there was a laceration, apparently made during the examination, through which some of the pus it contained had escaped into the recto- and vesico-vaginal pouches of the peritoneum: the latter presented no appearance of inflammation. From three to four small cysts, varying in size from that of a currant to that of a grape, existed just within the line of the incision. The kidneys were soft, large, and pale; the liver remarkably yellow, and the brain soft and unusually pale. In this case, as in the last, Mr. Brown attributed the fatal result to the impaired health of the patient, though she would no doubt have died ultimately of the suppurative discharge.

The third case was one of multilocular tumor, very large and adherent. The operation was performed. The contents of the cyst were highly albuminous. Soon afterwards inflammation in the cyst was set up. This was subdued; but the patient sank from exhaustion, the discharge having become offensive. Extensive adhesions anteriorly were found after death. The external wound was healthy. Mr. Brown remarked that, though this could not be called a successful case, yet the operation itself was satisfactory, and could not be assigned as the cause of death—an event which, in all probability, would not have been long postponed had no such attempt to relieve the patient been made.

Mr. Brown drew the following conclusions—1. That some cases are curable by pressure—namely, those in which the cyst is unilocular, without adhesions, its contents clear and not albuminous, and where the condition of the patient affords time for the requisite perseverance, no counter-indications existing. 2. That some multilocular cases, and such as present adhesions of the cyst, are to be materially relieved and retarded by pressure. 3. That in cases where pressure has failed, or is contra-indicated—whether the disease be unilocular or multilocular—but without adhesions, extirpation affords a means of cure; but in all such cases, before this severe operation is resorted to, time and the condition of the patient not opposing, pressure should be first tried. 4. That where the extent and character of the adhesions forbid extirpation, and where pressure is contra-indicated, or has been practised and failed—in such cases the lateral operation above described presents a means of cure having the greatest promise of suc-

cess. 5. That this lateral operation may be performed with facility, and is attended with little danger; no case of peritonitis having occurred to the author in the many instances in which he has had occasion to cut down upon and divide the peritoneum in the operation in question, and also in others.

In the discussion which followed the reading of this paper, the general feeling of the members was against the proposition. Mr. HIRD expressed his belief that patients suffering from ovarian dropsy had, generally speaking, a better chance of prolonged life by constitutional treatment, quiet, and the avoidance of local interference, than by resorting to any operative procedure.

November 16.

Case of Aneurism of the Aorta—Diagnosis.

Mr. CANTON exhibited a specimen of this disease, and read an account of the case as communicated to him by Mr. Leonard.

The patient was a female 37 years of age, who, about three weeks prior to her death, consulted Dr. Roe for difficulty of breathing, increased on going upstairs, pain in the arm between the shoulder and elbow, pain below the middle of the sternum, and through to a point under the middle of the left scapula, together with great depression of spirits. Late at night, on the 14th of April, 1850, Mr. Leonard was suddenly summoned to her, and found her with evident signs of collapse, accompanied with excruciating pain in the abdomen. She expired soon after his arrival. The body was examined 60 hours after death. The abdominal viscera were generally healthy, the lungs were gorged with venous blood, the pericardium contained a much larger quantity of fluid than is generally found, and the heart was fat and pale, with its muscular parietes thinner than usual. The aorta was extensively diseased as far as the first intercostal arteries; behind the left sigmoid valve, and above the left coronary artery, was a large orifice, the size of a shilling, leading into an aneurismal sac, which pressed upon the pulmonary artery, thus causing a diminution of its calibre. One of its sigmoid valves was so compressed, that half its pouch was obliterated. There were two other irregular openings above the orifice of the sac, but not communicating with it. One of the bronchial glands above the aneurism was ossified. The head was not examined.

Mercury in Syphilitic Eruptions.

Mr. HUNT read a paper on the mercurial treatment of syphilitic eruptions, in which

he contended—1. That mercury was capable either of curing or aggravating all these diseases, according as it was administered. 2. That none of them would get permanently and radically well without mercury. In reference to the first proposition, the author expressed his belief that mercury acted most favourably when its effect was sudden and intermittent, and that a continued course was liable to aggravate the disease. He believed the medicine would effect all its therapeutic benefits without irritating either the gums or the bowels, and he was accustomed to administer it in two or more successive and increasingly energetic courses, until the disposition to disease was destroyed. In reference to the second proposition,—viz., that none of these diseases, generally speaking, would get permanently and radically well without mercury, the author alleged that the apparent spontaneous recoveries were for the most part only temporary, and that the alternative or non-mercurial cures were equally unsound, and to be accounted for on the theory that, under favourable circumstances, the system was capable of tolerating the presence of an animal poison for a time, and sometimes even for life; but even in that case, the children of the patient were liable to become affected, and that, in fact, a very large proportion of cutaneous diseases now existing in England proved to be cases of hereditary syphilis, originally treated, in the parent, without mercury.

In the discussion which followed, Mr. B. Travers mentioned a case of secondary symptoms, in which inunction effected a cure, when the internal use of mercury to salivation only aggravated the local symptoms. In reply to various inquiries Mr. Hunt observed, that Mr. Travers' case was one of great interest, and he had frequently met with such. As regarded the signs of latency of the disease, the fact that it was latent rendered it impossible to detail them. A sufficient number of courses of mercury could alone, he believed, destroy the latency. He applied the term "syphilis" to that disease in which all the characters are present, and in their ordinary order. Every copper-coloured eruption is certainly not venereal, neither is every syphilitic eruption of a copper colour. Colour is no test of the disease. He urged the necessity of watching the effects of mercury more closely than had been practised, and coincided with Mr. Roberts and Dr. Golding Bird in the opinion, that in anæmic cases it was well to combine mercury with iron; and, in plethoric subjects, with evacuants and a reduced diet.

ACADEMY OF MEDICINE, PARIS.

Nov. 12, 1850.

Foreign Bodies in the Air Passages.

DR. RENDU, of Compeigne, transmitted the history of a case of this kind. On the 8th May, 1848, a child of five years of age, having a haricot bean in his mouth, suddenly uttered a cry, and was attacked with a fit of suffocation. This attack recurred frequently until the fifth day, when M. Rendu determined upon performing tracheotomy. The operation having been performed the suffocation ceased, but the foreign body was not expelled, although the incision was kept open for some time. It was then left to itself, and healed by the fifteenth day: after this time the attack of suffocation reappeared, but less severely. Three months afterwards, the bean was expelled in a violent fit of coughing. The attacks of suffocation ceased, but a cough with purulent expectoration followed. This gradually disappeared; and in September of the present year, two and a half years after the accident, the child is in a perfectly good state of health.

SURGICAL SOCIETY OF PARIS.

Nov. 13, 1850.

Pathological Anatomy of a Tumor on the Inferior Maxillary Bone.

M. CHASSAIGNAC stated that he had removed the growth from the maxilla of the patient he had presented at the last meeting of the Society. The operation was simple, and the tumor easily detached. The bone presented a deep depression, in which the tumor was lodged; the walls of the cavity were smooth and unchanged, the bone was simply gone, the nerve was exposed at the bottom of the hollow, the bone at the lower border of the cavity was quite thin. Hemorrhage took place from the surface of the bone, to arrest which the actual cautery was employed. The patient was recovering.

The tumor presented to the naked eye a firm fibrous envelope, and a yellow homogeneous dry texture internally. Under the microscope it exhibited, according to M. Lebert's report, the structure of fibro-plastic tissue, and, at some points, cells of a doubtful character, which might be suspected to be cancerous.

Umbilical Puncture in Ascites—Hernia of the Omentum.

M. DEBOUT referred to a case published

in the *Bulletin Therapeutique*, in which tapping having been performed at the umbilicus, and the opening having been enlarged with a lancet, the omentum became protruded, and could not be returned. Inflammation of the part took place, and extended to the peritoneum within the abdomen, terminating fatally.

A Tumor, difficult of Diagnosis.

M. FORGET exhibited a tumor removed from the axilla of a female. It was round, soft, elastic, moveable, and had been situated in the subcutaneous cellular tissue. At the centre of its surface was a nipple-like projection, which was made prominent by pressing the inferior portion of the tumor. The diagnosis of M. Forget was that it was a fatty tumor enclosing a cyst containing fluid. The majority of the members of the Society were of the same opinion. A section of the tumor exhibited a lipoma of a soft tissue, demonstrating the difficulty of diagnosis of tumors, and the circumspection required of the surgeon in pronouncing upon their nature.

BIOLOGICAL SOCIETY OF PARIS.

Monthly Summary, August 1850.

Cerebral Hemorrhage in consequence of Rupture of a Branch of the Middle Meningeal Artery.

DR. DUPLAY communicated the case of an old man, seventy years of age, of a middle stature, strong and well made, who had for some time manifested signs of mental derangement. On the 11th of July he left his home, and did not return as usual in the evening. On the 15th he was found by the police: having a bruise on his face he was taken to the hospital. On the 16th he was seen by Dr. Duplay. He was then evidently insane. There was no impairment of sensation or motion. The pulse was natural. The patient acknowledged to no headache. No external or internal injury, beyond the contusions on the face and legs, could be discovered. The patient was bled, and sinapisms applied to the extremities; quinine was given internally. On the following days severe rigors and fever occurred. His nights were restless, and he was constantly getting out of bed. On the 21st a swelling appeared, as large as a hen's egg, in the region of the parotid gland; the skin over it was of a reddish colour, and hard to the touch. A little below the ear a blister appeared, of a violet colour. On the next day the tumor had increased. The patient became comatose, and died on the 22nd.

On post-mortem examination it was found

that the parotid tumor when cut into exuded pus from the duct of every lobule. The integuments of the head presented no trace of the bruises. The bones, very carefully examined, discovered not the slightest trace of injury. On opening the cranium, an extravasation of blood was discovered between the left parietal bone and the dura mater. The hemorrhage had occurred from a branch of the middle meningeal artery. The inner plate and diploë of the parietal bone had disappeared, the outer table only remaining. Corresponding with this was a thin friable coagulum, which filled a solution of continuity in the dura mater. The arachnoid sac, over the left hemisphere of the brain, was lined with a thin layer of coagulated and liquid blood. The posterior surface of the brain through the cortical substance was died of a pinkish colour where it was in contact with the effused blood. The substance of the brain was healthy throughout.

M. Duplay considers that in this case fungoid disease of the dura mater had existed; that the fall occasioned rupture of the artery, and the fungoid disease being at the same detached was diffused in the extravasated blood.

ACADEMY OF SCIENCES, PARIS.

Nov. 11, 1850.

Contagion and Treatment of Scabies.

M. BOURGUIGNON read an analysis of a paper which he submitted as a supplement to his Essay on Scabies, to which the Montyon prize had been awarded in 1846. From his later researches M. Bourguignon had arrived at the following results:—

A. With regard to scabies transmitted from the horse to man—

1. That an undoubted and indisputable instance of this form of communication of scabies has not yet been produced.

2. That the patients admitted into the Hospital St. Louis as cases of this manner of communication have always presented the acarus and furrow peculiar to man.

3. That the acarus from the horse, placed upon the author's arm, and on that of another healthy individual, did not pierce the integument, nor give rise to any appearance of the disease: in fact, that its transmission from the horse is impossible. But it does not follow that other skin affections are not so transmitted.

B. On the contagion of the scabies from the dog to man.

Scabies has not yet been shown to be thus transmissible, although the skin diseases of this and other animals may be communicated to man.

C. On the transmission of scabies from man to animals.

The acari of scabies from man having been placed in considerable numbers on the skin of the cat, rabbit, sparrow, and rat, were observed to pierce the integument, but did not give rise to any trace of the disease. Whence the author concludes that the contagion of scabies to animals from man is impossible; that certain cutaneous affections are produced on the skin of man by contact with the same class of diseases of animals; and that their treatment does not involve the death of insects (insecticide), but should be conducted on general principles.

In the second part of his paper the author enumerated a series of experiments on the various remedies for scabies. The three principal remedies, *pommade de pou-dre et au soufre, huile de cade, et pommade sulfuro-alcalin d'Helmerick*, are superior to all others, and will cure the disease in forty-eight hours, if applied once thoroughly over the whole body every twelve hours for a quarter of an hour, followed, twenty-four hours after the last application, by a soap-bath. The patient should cover his hands well with the application before rubbing it on the rest of the body.

A New Property of Chloroform.

M. AUGEND, of Constantinople, transmitted a memoir, in which he pointed out a property that places a very distinct line of demarcation between chloroform and ether; this is, its power of disinfecting organic matters. M. Augend related the following experiment:—

Take three wide-mouthed flasks, the first containing a few drops of ether, the second a few drops of chloroform, the third left empty. If in each of these a piece of beef be placed, and the flasks be closed and left undisturbed in the summer season, the following circumstances will be observed:—The meat, which was of a reddish brown colour in its natural state, changed instantly to a vermilion-red in the mixture of chloroform and air, while in the ether vapour no change occurred. At the end of a week the difference was greater still; the meat in the flask containing atmospheric air was but little changed in its aspect; that in chloroform had acquired the appearance of boiled meat. On opening the flasks it was found that the meat, both in the atmospheric air and in the ether vapour, was putrefied, and emitted a most offensive odour; while that in the mixture of chloroform and air had the sweetish taste and odour of chloroform.

M. Augend has ascertained that 1-200th of chloroform completely prevents the pu-

trification of fresh meat. The most apparent action of the chloroform is the rapidity with which it traverses the thickest tissues, and causes an immediate contraction of their parenchyma, with consequent exudation of the fluids of the structure experimented upon. The author further dwelt upon the value, in a medico-legal point of view, that chloroform thus possesses in arresting putrefaction.

A new theory of the Production of Images on the Retina.

Dr. DEZAULIERS addressed a note, in which he stated the theory that the retina, in transmitting impressions to the brain, corrects the images which arrive on its surface—that it acts, indeed, as a concave mirror, which reverses the images which fall upon it.

Medical Trials and Inquests.

COURT OF ASSIZES, DARMSTADT.

March 11th—April 11th, 1850.

Case of the Countess of Goerlitz—Opinions of Baron Liebig and Dr. Bischoff on the alleged Spontaneous Combustion of the Body—Medical speculations on the Cause of Death—Conviction and Confession of the Criminal.

[Concluded from page 903.]

AT the trial of JOHN STAUFF, at the *first Diet of Assize*, which was held on the 11th of March, 1850, after the verification of the circumstances already detailed regarding the Countess's last movements, the discovery and extinction of the fire, the finding of the body, and the state of her apartments, on the requisition of the President of the assizes, Professors Dr. von Liebig and Dr. Bischoff, of Giessen, were conjoined with the members of the Hessian Medical College, and the following questions referred to this body of experts—viz. :—

I. In the foregoing circumstances is it possible, probable, or certain, that the death of the Countess of Goerlitz, and the state in which her body was found on the 18th of June, 1847, had been the consequences of the so-called spontaneous combustion?

II. In the foregoing circumstances is it possible, probable, or certain, that the deceased had perished from the influence of a fire external to her, and that she was exposed to such an influence, either—

1. Through an unfortunate accident; or
2. Intentionally from her own or another's deed?

III. In the foregoing circumstances is it possible, probable, or certain, that the deceased had not been exposed to the action of fire till after her death, and in this case is it to be admitted that she had perished—

1. By suicide; or
2. By the hand of another,—perhaps by the fracturing of her skull, or suffocation (throttling); or
3. From an attack of disease, or the occurrence of some unlucky accident?

IV. In the foregoing circumstances is it possible, probable, or certain, that the obvious source of the fire (the burning writing-desk) was the sole cause of the burning of the body of the deceased, or was any further cause necessary for the production of this burning?

V. Is verdigris to be considered as a poison, and to what extent would the use of the sauce drugged with verdigris, or a portion of it, tend to endanger the life or the health of the party partaking of it?

Report of the Commission of Experts, 27th March, 1850.—Question I. To this question the Commission returned an unanimous reply in the negative, considering that the case in hand was not an instance of spontaneous combustion. With the exception of Dr. Graff, they all go further, and contend against the reality and possibility of death being producible in this way at all, it being, as they conceive, an occurrence, 1st, not sufficiently established on historical grounds; 2dly, opposed to the known and acknowledged truths and laws of flame (inflammation) and combustion; and 3dly, incompatible with the known laws regulating the possibility and continuance of human life in health and disease. From these reasons Dr. G. dissents, contending for the abstract possibility of spontaneous human combustion, though admitting that the case in hand was not an instance of it;* while Drs. Büchner, Leid-

* In the appendix to the trial we have a formal defence by Dr. Graff (Zeitschr. Ergänz., pp. 126-149) of his dissent from his colleagues on this and other points. His reasons for believing in the abstract possibility of spontaneous combustion are based alone on the authorities adduced by him in his 2d Report (*ante*), and in that of Dr. von Siebold. These, however, are met by Professor Bischoff (Ibid. 3 V. H. pp. 181, *et seq.*), who has shown the little reliance which can be placed on these, as well as the unscientific assumptions involved by the admission of their credibility. The correspondence with MM. Regnault and Pelouse, and the Préfet of Police at Paris, adduced by Prof. von Liebig (Ibid. Ergänz., p. 159), has shown that the only modern case of spontaneous combustion—viz., that published in the "Journal des Débats," of February 24, 1850—was destitute of the very slightest foundation in fact. Vide also Ann. d'Hyg., Nos. 87 and 88, *passim*.

hecker, and von Siebold, yielded their assent to them, though opposed to their previous convictions, when brought forward by von Liebig and Bischoff during the discussions carried on in the Committee.

Question II. To this question the Commission also agreed unanimously in returning a reply in the *negative*, believing it to have been impossible, in the circumstances of the case, that the deceased's death could have been occasioned by the action of a fire from without. Further, none of the circumstances suggested, in order to account for her death in this way, appeared to them to be satisfactory. 1st. None of the facilities in favour of *accidental* death from this cause were present here. The upper garment was a woollen one. The kindling of her head-dress, her hair, or the upper parts of her clothes, by the fire, would not have been so fierce and sudden a catastrophe as to have prevented her from at least calling for assistance. 2dly. They hold it to be an impossibility that any one fully aware of the extreme tediousness and torture of such a mode of death could *voluntarily* resign himself to it. 3dly. They also hold that in general it would be difficult, admitting its bare possibility, for one individual to destroy another *against his will* by the slow action of fire—a supposition, besides, which receives no support from the known facts of the present case. In conclusion, they point to the absence of the usual signs of vital reaction on the surface of the body as favouring their general inference.

Question III. This question is unanimously answered in the *affirmative*: the body of the deceased was *certainly* exposed to the action of fire *after* death.

As regards the kind and manner of her death prior to the exposure of the body to the fire, no definite conclusion can, they conceive, be come to, with the imperfect and defective evidence now alone attainable, which affords grounds for only the following balance of probabilities:—

1. *Suicide* in the circumstances of the deceased they think improbable. Suicide by fire they hold to have been impossible. One of the known facts, indeed, is compatible with the assumption of suicide by some one of the more rapidly fatal narcotic poisons—such as prussic acid, morphia, or strychnia—and fire-raising for its concealment. The Countess, before taking the poison, might have set fire to the ottoman, the sofa below the mirror, and the writing-desk, and then lain down in front of the latter to perish by the deadly drug. The only support of this hypothesis is the absence of the keys; while its likelihood is

destroyed by the torn bell-pull, the smoke from the Russian stove, and the varied indications of the Countess's death prior to the outbreak of the fire. The moral bearings of the case also lend strength to the *objective* evidence—such as absence of motive to suicide, or indication of such an intention on the part of the deceased. Its proof or disproof, as far as the search for the above-mentioned poisons is concerned, would, after nearly three years' interment, be impossible as regards prussic acid, and as regards morphia and strychnia very problematical.

2. The commission consider it unlikely that the Countess had perished either by disease or accident. The only supposable diseases in this case would have been either apoplexy, syncope, or stupor, of some sort. Several general reasons may, they think, be urged against the probability of all or any one of these having occurred. The following apply to all the three:—

1. On different grounds they think it highly probable that the Countess's death had been prior to the return of the Count at half-past seven. He perceived no traces of fire at this time; and it is probable that it had broken out later than this. If this was correct, the deceased could not have caused the fire.

2. If the Countess in any of the conditions above enumerated (apoplexy, &c.) could have accidentally kindled the fire, a candle and candlestick, or some other burning body, must have been found in her vicinity, which does not appear to have been the case.

3. Supposing even that there had been a candle or other burning body near her when overtaken by death, syncope, or sleep, the upper part of the writing-desk or of its contents could thus alone have been kindled; while it is certain that the combustion of the desk had spread itself from below upwards, and not in the reverse direction. In opposition to this, should it be further assumed that the lower drawer had been standing open, it is inconceivable, as the folding-leaf of the desk was down, that the burning body could have reached the drawer beneath.

4. Setting aside the incomprehensibility of the assumption that the lower drawer had been in some way kindled, we must then admit in addition, that the dead, syncope, or stupefied Countess, had, while occupying her chair in front of the writing-desk, sunk down on the floor prior to the spread of the fire, since not the lower, but the upper parts of her clothes, and of her person, were laid hold of by it.

5. Neither of the above presumptions harmonizes with several other points in the evidence; such as the absence of the keys.

the torn bell-pull, the burning of the ottoman, and the smoke from the stove.

Besides the above general objections against death from disease or accident, special reasons, on a closer inquiry, suggest themselves as bearing against the individual diseases presumed.

(1) The uniformly vigorous health of the Countess up to the time of her death, her habit of body, and her little advanced age, rendered the occurrence of any form of apoplexy in her case unlikely.

(2) Syncope would not have been immediately and directly fatal, and the spread of the fire would have tended to have roused her from such a state.

(3) Opposed to the supposition that the Countess, in falling asleep at the writing-desk, had accidentally set fire to it, had thus been first stupified, then suffocated, and afterwards dropped from her chair and been burned, we have the following considerations:—Such a slow combustion as is here supposed would have diffused around such a volume of gaseous products of a noxious and, in the end, destructive kind, calculated to irritate in the highest degree the organs of sense and respiration, as would of itself have roused a sleeping person, and compelled him to have taken measures for his relief.* Charcoal alone burns without giving out smoke or smell, and generates a very stupifying, and at length destructive alteration of the atmosphere.

3. That, in fine, the deceased had perished by the hand of another they consider to be possible and probable, not merely from the failure and exclusion of the other probabilities, but on direct grounds. In this category they reckon—

(1) The combustion of the body, for the effecting of which a second party was, they are convinced, absolutely necessary, as will appear by their reply to Question IV.

* We are not a little surprised at the ignorance shown in this argument of facts well known in this country. Dr. Alfred Taylor has recorded several cases of persons who had been suffocated in this way (vide *Man. of Med. Jur.* p. 739, and *Treatise on Poisons*, p. 795.) We have ourselves met with two instances of accidental death from suffocation from the smoke of burning buildings. In the first of these, five persons thus perished; and in the other, one adult woman. In the former of these accidents the parties were of various ages, from eleven to sixty years, and all, with, perhaps, one exception, had gone to bed sober, when within an hour the house was in flames, and some time elapsed before their dead bodies were got out of the building. What makes this illustration of the fallacy of the above argument the greater is, that the house in question was one of those old-fashioned ones, the walls of which were panelled throughout with wood. The combustion here was not, therefore, from coal fires, as in most of our published cases. In four out of these six cases the vault of the cranium was extensively deficient, as in the Countess's body, and the heads of some of the late . . . the limbs protruded.

(2) The position of the tongue. Though, from being uncertain what effect the action of the fire on the hard and soft parts of the face would have had in leading to the protrusion of the tongue, they do not consider the inference that it was necessarily caused by suffocation to be based on sufficient data, yet they are not prepared to combat the possibility of suffocation, and its connection with the position of the tongue.

(3) The fissure in the right temporal bone. This they consider fully as possible to have been the consequence of a blow on the head as of the effect of fire.

(4) The fragment of stuff* coloured with what was conjectured to be blood-stains. On this they lay little stress, from the nature of the stains not having been determined by chemical or microscopic examination.

On the whole, therefore, they are inclined to attribute the Countess's death with greater probability to the effects of a blow than to suffocation. They are not altogether satisfied of the possibility of a very powerful and strong man being able to seize and directly strangle such a woman as the Countess in the waking state. That she could have been overpowered during sleep they consider as quite unlikely, as she was in the custom of locking herself in on such occasions. From her habits of body and mind, she was a person likely to have made a powerful struggle for life. The conjecture which has the most probability is, that she had been first stunned by a blow, and then suffocated.

Question IV. The Committee were divided on the solution of this question. The minority, consisting of Drs. Graff, Leidhecker, and Rieger, did not conceive it likely that the combustion of the writing-desk alone would have sufficed to produce the burns on the Countess's body, and deemed it probable that some other and further cause was necessary to their production; while the remaining members of the Commission, constituting the majority, considered it both possible and probable that the apparent cause—the burning of the desk—was the real and sole one.

The opinion of the majority rested upon data both of a positive and negative kind.

1. The positive data assigned by them are as follows:—

(1) The temperature and amount of heat generated by the combustion of the writing-desk was sufficient to have caused the burns at the upper part of the Countess's body at the distance of about two feet from it. Two separate and independent calculations gave the bulk of the wood,

* A piece of linen found in the privacy of the house.

partly fir and mahogany, but chiefly oak, thus consumed to have been 7 Hessian cubic feet (3·863 cubic feet English), which, reckoning the cubic foot at the minimum of 18 Hessian lbs. (19·838 Eng.) would amount to 126 Hessian lbs. (138·83 lbs. Eng.). Of the wood, however, a residue equal to 2 cubic feet (1·103 Eng.) of charcoal was left unburned, which, at 7 lbs. Hessian per cubic foot, would correspond with 60 H. lbs. (66·12 lbs. Eng.) of wood. Sixty-six Hessian lbs. (72·73 lbs. Eng.) would have thus been burned, giving out a temperature of 184,800° C. (332,672° F.) Now the medium weight of a woman's body from 40 to 50 years of age amounts to 118 Hessian lbs. (124·526 lbs. Eng.) Assuming, further, that one-fourth of the weight of the Countess's body, thus calculated, was desiccated and reduced to the state of cinder, we have only from 7 to 8 per cent. of the heat required for this purpose, leaving 9·10ths, or nearly 171,780 C. degrees of it (*i. e.*, 309,236° Fahr.), which would serve to elevate the temperature of the 7617 Hessian cubic feet of air (4257·68 Eng.) in the parlour and closet. This calculation, moreover, can only be considered as the minimum temperature, as it leaves out the effects of the combustion of the other articles in the writing-desk, sufficient data for the calculation of these being wanting. Besides, the heat generated had sufficed to melt gold, silver, and iron, some of which metals require a temperature to effect their liquefaction of upwards of 1000° C. (1832° F.), while a heat of from 800° to 400° C. (572° to 752° F.) will char and ultimately burn animal matter. Again, stearine candles were melted at the distance of from 9 to 27 feet, which presupposes an atmospheric temperature of at least 58° C. (136·4° F.) Further, several chairs were burned which were at a greater distance from the fire than the dead body. Now it appears from the experiments of H. Merck, that a temperature closely bordering on the melting-point of lead is requisite to char paper and organic matter; and hence, if the heat given off by radiation from the burning desk acted on the surface of the chair at the distance from it at which it stood, it must have had a temperature at least as high as the melting-point of lead. Finally, one of the witnesses stated that the frame of the looking-glass, at about 16 feet from the fire, was so hot at the time that he could hardly bear to touch it.

(2) The time during which the combustion of the writing-desk had lasted was sufficiently long to have affected the body in the way described. It appeared to them that the burning of the writing-desk had commenced after the Count had gone out,

about half-past seven, which, as it had gone on till 11 P.M., or from 3 to 3½ hours, allowed a sufficient time for the effects of it on the body to have been produced. It is also to be noticed that at one period—*i. e.*, while there was still enough of fresh air in the room to maintain it—the combustion of the desk must have been very active, judging from the entire destruction of the folding-leaf, if we except a fragment of it left at the lock. The heat from the folding-leaf must have been the main cause of the desiccation of the body, the charring of it afterwards requiring less of the remaining caloric.

(3) The posture of the body was in the highest degree favourable to its combustion. It had lain immediately in front of, and at about two feet distant from, the writing-desk. The radiant heat would have been entirely concentrated on the body from the sides, the upper and lower parts, and especially the folding-leaf of the desk.

(4) The form of the burns corresponded with the assumption that these must have occurred at the spot where, and in the position in which, the body was found. The position of the body was more clearly evinced by the extent, situation, and limits of the burns, than by the depositions of the witnesses, and they even think that the head must have been closer to the fire than they had supposed.

(5) An experiment was undertaken at Giessen,* with the express object of imitating, as closely as possible, the burning of the Countess's body, when it was demonstrated, by means of the head of a human subject, that the burning in the present case could have been produced by the writing-desk, and in the position in which the deceased was found, particularly if the papers, articles of dress, and other combustible matters contained in this repository, were taken into account.

2. *Negative data.*—Besides the positive proofs that the burning of the Countess's body was caused by the combustion of the writing-desk alone, the majority of the Commission point to the following negative grounds on which they believe it partly impossible, partly in the highest degree improbable, that any other and further combustion, and through a second party, was necessary for this end.

(1) If the deceased, after being murdered, had been burned in the servants' room—from the chimney of which, as well as that of the parlour, smoke had been observed to issue on the night of the fire—the transport of the body, they think, particularly after a death of violence, could

* The details of this experiment are given in the Appendix (Zeitschr. Ergänz. p. 140). Vide also Ann. d'Hyg., 66 no., p. 400.

not have been managed without leaving some traces behind it, none of which were anywhere found.

(2.) The following circumstances negative the combustion of the body by alcohol, oil, charcoal, or wood, within the Countess's room.

(a.) The manipulation requisite for this, the adjusting of the fire, the necessary alteration of the position of the body, the employment of props for the head and chest in succession, and the special preparations for the burning of the upper extremities, as they were found burnt, could not have been accomplished by an unassisted individual. Any one of these manipulations would have demanded preparatives which would have left traces on the floor, the tables, chairs, the utensils, or other objects, which the closest scrutiny failed in detecting.

(b.) No supposable manipulation and change in the positions of the body will be found to be consistent with the form of the burns on the head, arms, chest, or even on the clothes.

(c.) It seems impossible that any person could have remained shut up in the comparatively small apartment of the Countess during the combustion of her body and clothing. He could neither have opened the doors nor windows for fear of detection, nor have remained in the room in the midst of the products of combustion, nor returned to it had he left it for an instant, on account of the smoke, vapour, and heat. He must besides have had time to change his dress, clean, and wash himself, to get rid of the smell which would have adhered to him, which even as it was had nearly betrayed him.

(d.) The combustion of the Countess's body by alcohol is opposed to these considerations:—

(aa.) The quantity of it that would have been required. The burning of the head alone would have demanded 3 maas of spirit (6·34 wine pints). To burn the chest and arms a still greater quantity of it would have been needed; and to place these parts in the spirit-flame, a much greater portion in reserve.

(bb.) Admitting even that 3 maas of alcohol was sufficient, the following calculation proves that a person could not have remained shut up in the room during its combustion. The parlour and closet contained 1,512 H. cubic feet (833·11 cubic feet, Eng.), to 68·64 lbs. H. (75 504 lbs. Eng.) The 3 maas of alcohol at 80° weigh 104 lbs. H. (11·775 lbs. Eng.), and contain 8·6 lbs. H. (9·46 lbs. Eng.) of absolute alcohol, for the combustion of which 20·64 lbs. H. (22·704 lbs. Eng.) of oxygen would be required. The oxygen of the air in the

room would be thus brought down from 21 to 14 per cent., which being much less than is contained in expired air, would no longer support life.*

3. The period of time at his disposal could not have admitted the interposition of other combustibles. From the time of the Count's leaving the house and the return of one of the servants, less than an hour elapsed (i. e., from half past 7 and twenty minutes after 8), too short a time to prepare and execute the combustion of the body, and then to obliterate all traces of the act. They cannot forget that the burning of a head alone with spirit of wine required an hour and a quarter.† The criminal must have been in constant dread of interruption, and could scarcely have meditated such an operation.

4. They cannot forbear expressing their doubt on psychological grounds that any one could be found capable not only of committing a murder, but likewise, under the pressure of its guilt, of also accomplishing such a complicated and fearful operation as the combustion of the body, by means of alcohol, &c., while it was so much easier for him after it was over to obliterate its traces by an ordinary fire-raising.

In concluding their reply to this question, the majority of the Commission express their opinion regarding the burning of the ottoman.

This combustion of the ottoman may have occurred, they conceive, accidentally, with the view of an ordinary fire-raising, or to get rid of blood-stains.

The *minority*, while they express their opinion to be that the combustion of the writing-desk was more than sufficient to produce the burns on the Countess's body, yet contend for the necessity of some further agency, on grounds which appear to be of a very slight kind. Their strongest argument is the one they draw from the circumstance of finding it impossible to fire the horse hair cover and stuffing of the ottoman.

Question V. In answer to this question the Commission unanimously conclude, that the verdigris in the sauce would have occasioned no serious or lasting effects on the life or health of the person swallowing it.

At the diet of the assize on the 11th of April, 1850, John Stauff was found guilty of the murder of the Countess of Goerlitz, and of the subsequent fire-raising, and

* This implies that the room was so closely secured that no one could enter from without.

† The reference here is to an experiment by Dr. Graff and others, to ascertain the possibility of the alleged combustion of the Countess with spirits of wine (*Zeitschr. Erganz.* p. 153. *Ann. d' Hyg.* No 83, p. 407).

attempt to poison, and sentenced to imprisonment for life.*

Correspondence.

HOMEOPATHIC HYPOTHESES, AND CHRONIC POISONING BY LEAD.

SIR,—As you have published in your journal of Oct. 25th, 1850, p. 717, and at the same time politely noticed my letter to you, I venture to suggest that your remarks do not meet my argument. The argument was not that, because a half-millionth part of a grain of lead would affect the system in health, that *therefore* a decillionth part of a grain of medicine would act on the human healthy body. The homœopathsists, so far as I can judge from their works (and I am indebted to a review in your journal of the work published by the English Homœopathic Association, "Homœopathy and its Principles Explained," for greater acquaintance with homœopathy), do not maintain, if I understand their views aright, that "a decillionth taken at one dose will be as potent in its effects on the system as a half-millionth proportion of the carbonate of lead diffused through water which is continued daily for weeks and months together, the lead acting not by its small proportion, as contained in the water, but by its special accumulation in the system." They maintain that a decillionth part of a grain of medicine, the powers contained in which have been developed by the process of preparation to which the medicine is subjected previous to use, when taken by a person with a disease to which the remedy is in homœopathic relationship, is potent against the disease. This you, as a logician, must acknowledge, is a proposition widely different from that which you put forth, your proposition being one which, I presume, no homœopathist would dispute.

I regret to find you still maintain that twelve jurymen are to be judges of a medical question. "A homœopathist treating a case according to the globular system resembles an orthodox practitioner who

professes to treat it with pills of *mica panis*. In the event of death in either case, there should be a coroner's inquest."

How is the question to be considered? If death, following any treatment, is to be proof that the death was caused by the treatment, then all deaths should be inquired into. But suppose a case of pneumonia died under homœopathic treatment, which is likely to occur, as cases die under all treatment (I find in your journal of Oct. 25 that 53 died in one week of pneumonia), and the question was to be considered by a Coroner, how is he to decide whether the treatment was correct or not? Is he to argue the question *a priori*, and to say, "It is contrary to common sense to attempt to cure diseases by infinitesimal doses of medicine, and therefore the treatment was wrong and criminal?" What would be the answer of the homœopathist? What but this?—I can prove, by witnesses who have been cured of pneumonia by infinitesimal doses of medicine, that infinitesimal doses of the appropriately-chosen medicines can cure pneumonia.

Could any Coroner, being a lawyer, presume to dispute such evidence? I have often thought it would be highly beneficial to have a verdict of "Manslaughter" passed against a homœopathic practitioner for treating an acute disease with infinitesimal quantities, and not succeeding with the given case (but do not put the homœopathist in Newgate, as was Mr. Pearce by Mr. Membury Wakley), and then let the question, if it is to be discussed and decided by twelve jurymen, but not Coroner's jurymen, be discussed fully and freely, and with all the sifting of evidence which legal acumen and medical skill can bring to bear upon the subject. Let me conclude this note by a quotation from the life of Dr. Andrew Combe, by his brother George Combe: it is part of a letter to Dr. Forbes, p. 483:—

"I cannot get over the extreme improbability of such visionary doses having palpable effects. But then we are too ignorant to decide what *may* or *may not* be in nature; and you admit that you have men of great talent, skill, learning, experience, and honesty, affirming their actual experience of active results, and can oppose nothing to that affirmation except your opinion. I have often said that, were I in practice, I should feel myself bound to test homœopathic practice. It has established its claim to a fair hearing, and only useful knowledge can come out of an impartial and adequate trial of its powers."—With this quotation,

I beg to remain, sir,

A CONSTANT READER AND
SUBSCRIBER.

* We copy the following notice from an English newspaper of date, 7th September, 1850:—
"John Stauff, condemned to perpetual imprisonment for having assassinated the Countess of Goerlitz at Darmstadt, has just confessed his crime. He declared that he had entered the room of the Countess to announce to her that he was going out, when, finding no one in the room, he was tempted by the articles of value he saw there to commit a robbery. While doing so the Countess came in: a struggle took place, and he seized her by the throat and strangled her. He afterwards placed the body on a chair, and putting round it a quantity of combustible articles, set fire to them."

his views freely; but when he admits that he is a believer in the assumption that the decillionth, or any other *illionth*, part of a grain of any substance whatever can have medicinal powers developed in it by "the process of preparation," and that it will cure a disease according to an alleged homoeopathic "relationship," we have no common ground of argument. The same amount of faith would justify a full belief in the potency of amulets and charms. No homoeopathic practitioner has any means whatever of knowing that he is prescribing any medicine, as he cannot prove its existence in the globe, and he is obliged to place implicit reliance upon the statement of some other person that the medicine is there. Shake up a box of homoeopathic globules, and you have no means of distinguishing sulphuric acid from charcoal, or belladonna from gold! If we are to rely upon supposed effects merely, we may, as well believe in the cure of diseases by amulets and galvanic rings. But it was lately shown, by a case reported in this journal, that when these alleged potent globules were administered to a patient without her knowledge they had no effect whatever; it was only when she took them *knowingly* that certain effects followed. We refer our correspondent to the case reported at p. 82 of the present volume.

THE STANDARD LIFE ASSURANCE OFFICE
AND MEDICAL REFEREES.

SIR,—Allow me to request the favour of your inserting in your next publication, if convenient, the following remarks with reference to a letter from Mr. J. H. Houghton, surgeon, of this town, which appeared in your paper of the 25th October last, but which has only come under my notice to-day:—

As the object of Mr. Houghton's communication appears to be to create an impression that the Standard Life Assurance Office has, in the transaction he refers to, admitted through me, its agent here, the equity of the claim set up by certain members of the medical profession to the payment of a fee by the Office, for answers given relative to the health and habits of their patients who may wish to assure their lives in such offices, I consider it my duty to explain the case which occurred between me and Mr. Houghton more fully than he has done, so that erroneous inferences may not be deduced.

When I called upon Mr. Houghton, at the time he states, to induce him, if possible, to alter his views respecting the question in dispute, I distinctly told him that the Company would not sanction my paying, on *their* account, the fee (10s. 6d.)

which he demanded, and that, if I did pay him the amount, I must do so out of *my own pocket*.

After some discussion, however, it was at length proposed by Mr. Houghton (to convince me that he was not actuated by selfish motives) that, if I paid him the half-guinea, he would give it to the Dudley Dispensary, or I might, if I thought fit, pay it myself to the Secretary of that Institution.

This offer I agreed to, and subsequently I paid Mr. Houghton the above-named sum to be so applied, and, when I left him, I stated that I should be happy to pay him in such cases similar sums to be so appropriated, never for a moment intending to intimate a readiness on the part of the *Standard Company* to pay any fees beyond those of their *own* medical officer, because that would have been acting in direct contravention of their repeated instructions, and a course too unbusiness-like for me to have pursued.

I have therefore to assure Mr. Houghton that the money which I paid him for the benefit of the Dudley Dispensary, and the fee which I paid to his "brother practitioner," were paid out of my own purse, and that I have not been, and never expect to be, reimbursed by the Office for such payments.

Under these circumstances, therefore, Mr. Editor, I think you will admit that the medical profession have no cause for congratulating themselves on having achieved any victory over the principles of the non-paying Assurance Offices.

I am, sir,

Your obedient servant,
J. B. FISHER.

Dudley, 20th Nov. 1850.

P.S.—I should, perhaps, mention that the occurrence above alluded to took place in the year 1849, so that Mr. Houghton has been somewhat tardy in bringing forward his remarks upon it. J. B. F.

DEATH FROM CHLOROFORM.

DR. ASCHENDORF states that a child, one year old, had been operated upon for a *nævus* under the influence of chloroform; with apparent success, when, on the child being removed from the table, its head fell back, and it instantly died in a state of convulsion. The quantity used had been six drops in the first instance, and a second application of three drops in some tow placed in a cup.—*Casper's Wochenchrift*, Sept. 6th, 1850. x

Medical Intelligence.**UNIVERSITY OF LONDON.**

M.B. SECOND EXAMINATION—1850.

Examination for Honours.

Tuesday, November 19.—Morning, 10 to 1.

*Physiology and Comparative Anatomy.**Examiner, Prof. CARPENTER.*

1. Describe the Anatomical elements of an ordinary *Mucous Membrane*; and state the principal modifications which these undergo in different organs.

2. Show the dependence of all *Vital Action* upon *Heat*, by examples drawn from different classes of Animals; and give an account of the chief provisions which are met with for its constant or occasional development in the living body.

3. Describe the *Nervous System* of an *Insect*, in its three states of Larva, Pupa, and Imago; point out its anatomical relations to that of Vertebrated Animals, and give an account of the probable nature of its actions, as elucidated by observation of the natural habits of the class, and by experimental observation.

Afternoon, 3 to 6.

*Physiology and Comparative Anatomy.**Examiner, Prof. CARPENTER.*

1. Give a general account of the process of *Respiration*, as performed in the Human subject, specifying the minute structure of the air-cells of the Lungs, and of their capillary network; the mechanism by which the air contained in them is continually renewed; the parts of the nervous system by whose action the movements are sustained; the average quantity of air that passes through the lungs per minute; and the nature and amount of the changes of composition effected in it by the respiratory process.

2. Describe the structure of the *Electric Organs* in the Fishes which possess them, and enumerate the principal phenomena of their action, pointing out the dependence of these upon Nervous agency.

3. Give an account of the Microscopical characters of the different forms of the *Nervous Tissue*, and of its chemical composition; state what may be probably regarded as their respective functions, and how far these are dependent upon oxygenated blood; and point out the relations between Nerve-force and Electricity.

Wednesday, November 20.—Morning, 10 to 1.

*Surgery.**Examiners, Sir STEPHEN HAMMICK and Mr. HODGSON.*

1. Give the different diseases of the Testicle, whether they arise from natural or accidental causes; you will describe the appearances, symptoms, and treatment, of each variety through its several stages; and when the testicle requires to be removed, you will give the method of performing the operation of Castration, with the subsequent management of the case, both locally and generally, under favourable and untoward symptoms.

2. Describe the various Polypi of the Nose and its communicating cavities, whether of a mild or malignant character: you will give the situation, attachment, appearance, symptoms, and mode of treatment, of each variety of Polypus, with the probable termination: you may further illustrate your observations by the detail of any cases which may have fallen under your notice.

Afternoon, 3 to 6.

*Surgery.**Examiners, Sir STEPHEN HAMMICK and Mr. HODGSON.*

1. Give the local and general treatment of a compound fracture of the Thigh-bone, about its middle third, whether arising from falls, blows, or gun-shot: and when it is decided to amputate the Limb, either immediately after the receipt of the fracture, or any subsequent period, you will give your reasons for such decision: you will describe the method of performing the operation of Amputation, with the subsequent management of the patient, both locally and generally, when under favourable or the dangerous symptoms arising from exhaustion, inflammation, suppuration, sloughing, hæmorrhage, or any other cause.

2. Enumerate the various diseases to which the lower part of the Rectum and Anus are liable: give the method of performing the operation required for a fistula in Ano, when in a simple or complicated form, with the subsequent treatment of the case according to the symptoms which are likely to arise.

Thursday, November 21.—Morning, 10 to 1.

*Medicine.**Examiners, Dr. BILLING and Dr. TWEEDIE.*

1. Sketch the more recent views as to the modes by which pus may be introduced into the blood. Describe the pathological causes, diagnostic symptoms, and treatment of Pyæmia.

2. Describe the morbid appearances in the brain in fatal apoplexy.

Afternoon, 3 to 6.

Medicine.

Examiners, Dr. BILLING and Dr. TWEEDIE.

1. Describe the principal varieties of morbid structure usually classified under the term *dropsy of the ovary*. What are its diagnostic signs?

2. Sketch the causes and the indications of treatment in the lithic, phosphatic, and oxalic diathesis respectively.

Friday, November 22.—Morning, 10 to 1.

Midwifery.

Examiner, Rr. RIGBY.

1. Describe the prophylactic treatment of abortion.

2. What is the meaning of a Mole Pregnancy?

3. What are the sources of danger to the Child's life in face and nates presentations, and how would you act under such circumstances?

4. Give the diagnosis of true from false pains.

RAVAGES OF THE CHOLERA IN THE WEST INDIES.

By intelligence just received from Jamaica it appears that the cholera was raging fearfully in Kingston, Port Royal, and St. Catherine's; and, up to the time of the packet's departure, the deaths in Kingston averaged at least 30 a-day. The latest official accounts published up to the morning of the 27th of October showed a total of 266 deaths in Kingston alone. In Port Royal and St. Catherine's the actual numbers were less; but, compared to the population of Kingston, the mortality has been far greater, particularly in Port Royal, where about an eighth of the population has been cut off. The deaths in all parts, with two or three exceptions, occurred among the lower orders of the black people, some of whom resided in miserable hovels and damp localities. Up to the last account received in Kingston, the north side of the island was free of the disease. An order has been issued by the Governor in Council forbidding communication coastwise between Port Royal and Kingston, and the uninfected ports, under certain restrictions. The authorities were particularly vigilant in the uninfected districts as well as the others, and the most stringent sanitary regulations were being generally adopted. In all districts the want of medical men was much felt. Kingston, with a population of some 40,000 inhabitants, contains only ten doctors, who, in addition to their private business, have in various instances to

attend the public prisons and institutions. Spanish Town contains but three doctors, and Port Royal none at all. At the latter place the services of the surgeons attached to the Royal Army were secured through the influence of the Kingston authorities. Our correspondent assures us that, should the disease make its appearance in the country districts, the mortality is likely to be alarming, as there is not to be found, in some of them, a doctor for twenty miles round. One of the Kingston newspapers (the *Daily Advertiser*) writes on the positive necessity of the lower orders being "compelled" to contribute to the support of a resident medical man in the respective parishes.

The state of alarm in which the public are at Kingston cannot be described. The poorer classes are in an awful state of destitution, and in some parts of Kingston and Port Royal whole families have fallen victims to the scourge within a few hours. Independently of the presence of cholera, the town was otherwise unhealthy, fevers and other diseases having appeared.

Further advices from Jamaica to the 31st ult. announce that the cholera was still raging with great virulence. The Kingston returns for the 28th report 53 new cases, 18 recoveries, and 30 deaths—remaining 85: at Port Royal 21 new cases, 3 recoveries, and 11 deaths—remaining 34. Sanitary measures were being actively carried into effect.

THE SANITARY STATE OF THE CITY.

ACCORDING to the Report presented to the City Commissioners by Mr. Simon, on Tuesday last, it appears that the deaths during the 52 weeks ending the 28th of September, 1850, in the city of London, were 2,752, and the rate of mortality was estimated at somewhat less than 22 deaths out of every thousand living persons; while under the ravages of the pestilence of last year the general death-rate had risen to the height of 30 in 1000.

POISONED GAME.

WE have already directed attention to the public sale of poisoned game, and the danger which might arise from using as food such as have not been shot. The following letter shows that the practice still continues in the London markets:—

"A friend of mine purchased at a shop and presented us with a brace of partridges; to-day we had them dressed, and they were partaken of by myself, my wife, and little boy, the remains being finished by our servant. About an hour after dinner I was seized with pains in the stomach, giddiness and pain across the forehead, accompanied by a metallic taste in the mouth,

evidently betokening the presence of some mineral poison: these symptoms continued, more or less, for three hours, after which their virulence surrendered to medicine, but still leaving me very unwell. My wife partook very sparingly, and was not affected; my little boy, who ate more, complained of similar pains in the stomach, but was not ill; our servant, on the other hand, soon after I was attacked became very unwell, and suffered from very much the same symptoms as myself. Whilst at dinner, I remarked, 'These birds have not been shot; they have been caught in some way.' I have now no doubt whatever that the partridges in question were taken with poisoned wheat or other grain; and for the future, in selecting partridges, pheasants, &c., I would strongly urge the public to choose those that are evidently shot, which can easily be ascertained on examination, such as by broken legs or wings, or shot-marks in the head, neck, and other parts of the body, and never pick out those birds that look clean, and whose plumage is unbroken.

DISCOVERY OF THE MAGNETIC PROPERTIES OF OXYGEN GAS.

At the last monthly meeting of the Royal Institution, Mr. Faraday announced to the members present his discovery (the subject of a paper sent in to the Royal Society) that oxygen is magnetic, that this property of the gas is effected by heat, and he believes the diurnal variation of the magnetic needle to be due to the action of solar heat on this newly-discovered characteristic of oxygen—the important constituent of the atmosphere. We do not mean to give the above as the terms of Faraday's announcement, or as the exact facts of the conclusions drawn from his last experimental researches, but only as a foreshadowing of the new results and views of one of our most eminent British philosophers. We must add, however, that Becquerel also has recently directed attention to a somewhat similar conclusion; he communicated to the Academy of Sciences at Paris, that oxygen is magnetic in relation to the other gases, as iron is to the rest of the metals, and inferred that it is probable or possible (we have not the paper by us to refer to) that the diurnal variation may be connected with this property of oxygen.

POOR-LAW MEDICAL RELIEF IN IRELAND.

ACCORDING to a report to Parliament, printed on Saturday, there were 468,028 hospital patients admitted in the year ending the 25th of March last. The average number under treatment per week during the year was 34,072, and the expenditure in the year was £177,039. 11s. 9½d.

for medical establishments under the Poor-Law in Ireland.

STATISTICS OF LUNACY—ANNUAL REPORT.

ON Saturday last was issued the fifth Annual Report of the Commissioners of Lunacy. The Report, which is addressed to the Lord Chancellor, was signed by Lord Ashley on the 30th of June last. It appears that on the 1st of January there were 15,079 lunatics in asylums, hospitals, metropolitan licensed houses, and provincial licensed houses, of which number 11,305 were paupers and 264 criminals. Out of 454 lunatic patients attacked by cholera 311 died.

MICROSCOPICAL ANATOMY.

MR. GOADBY, so well-known by his minute dissections at the Royal College of Surgeons, is at present engaged in giving a series of demonstrations on microscopical anatomy in Philadelphia, U.S.

OVIARTOTOMY.

THE New York Medical Gazette of October 19th, announces that Professor E. R. Peaslee has successfully removed an ovarian tumor, weighing twenty-four pounds.

AMPUTATION OF THE THIGH NEAR THE HIP-JOINT.

THIS operation was performed on Saturday week, at the Westminster Ophthalmic Hospital, by Mr. Guthrie, junior, in the presence of many London surgeons. It was not found necessary to remove the head of the bone. The operation was required for the removal of a malignant tumor of the thigh.

SUCCESSOR TO PROFESSOR WEBSTER.

DR. E. N. HOESFORD has been appointed to the Chair of Chemistry, in the Massachusetts Medical College, in lieu of the ill-fated Professor Webster.

ELECTION OF SURGEON TO THE GENERAL HOSPITAL NEAR NOTTINGHAM.

At a special general meeting of the Governors of the General Hospital near Nottingham, held on Thursday, Nov. 21st, Booth Eddison, Esq. F.R.C.S., was elected surgeon to the above Institution, vice G. M. White, Esq., who has resigned the appointment from impaired health.

TESTIMONIAL TO DR. CANHAM, OF RAMSGATE.

A PUBLIC DINNER was recently given to Dr. Canham, of Ramsgate, on the occasion of his retirement from practice in that town; and on the 25th inst. a handsome testimonial in plate was presented to him at the Town Hall. It consisted of four elegant inscriptions for this purpose.

amounted to £175, received from 140 subscribers. Dr. Canham has been in practice at Ramsgate for a period of twenty years, and has earned the good opinions of all.

CONSUMPTION CURABLE.

THE following advertisement, taken from a daily paper, is a curiosity in its way. It is a new feature in quackery to find one of the "cured" occupying the chair in a public institution:—

"CONSUMPTION.—Dr. COFFIN will deliver the TENTH LECTURE of his COURSE, being the second on CONSUMPTION, at the British Institution, Cowper-street, Finsbury, on Tuesday evening, 26th inst., on which occasion, Mr. Winchester, of Vauxhall-road, recently cured of consumption by Dr. Coffin, will take the chair. Several persons will also be upon the platform who have been cured of the same disease."

APOTHECARIES' HALL.

NAMES of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, 21st November, 1850:—James Stoate, Bristol—Edward Adolphus Brown, Chelmsford—Joseph Wilson Beaumont, Sheffield, Yorkshire—Thomas Young Thompson, Sherburn.

OBITUARY.

MR. DORRINGTON.

WE regret to announce the death of Mr. Dorrington, which took place at Manchester on the 5th inst. The deceased was in his 33rd year, and had already acquired a high reputation in his profession. The immediate cause of death was water in the chest. The deceased was greatly respected by his brother practitioners in Manchester, a large number of whom followed him to his grave.

DR. JOHN TAYLOR.

ON the 22d inst., at 72, Upper Berkeley-street, Portman-square, Dr. John Taylor, late surgeon in the army, in the 80th year of his age.

METEOROLOGICAL SUMMARY.

Mean Height of the Barometer 29.34
" " Thermometer 46.9
Self-registering do. Max. 57° Min. 37°
" From 12 observations daily. " Sun.

RAIN, in inches, 1.02.—Sum of the daily observations taken at 9 o'clock.

MEMOROLOGICAL.—The mean temperature of the week was 4° above the mean of the month.

BIRTHS & DEATHS IN THE METROPOLIS During the Week ending Saturday, Nov. 23.

BIRTHS.	DEATHS.

The following is a selection of the numbers of Deaths from the most important special causes:

Small-pox	11	Convulsions	41
Measles	26	Bronchitis	77
Scarlatina	41	Pneumonia	54
Hoping-cough	36	Phthisis	111
Diarrhoea	18	Lungs	13
Cholera	1	Teething	14
Typhus	47	Stomach	5
Dropsy	19	Liver	6
Hydrocephalus	26	Childbirth	9
Apoplexy	28	Uterus	1
Paralysis	23		

REMARKS.—The total number of deaths was 39 above the average mortality of the 47th week of ten previous years.

NOTICES TO CORRESPONDENTS.

D. R. should read with more attention when he indulges in hyper-criticism. Our comparison of the period of education required by the English College of Surgeons with the period required by the Colleges of the United States referred obviously to the education of surgeons generally, i.e. of those who constitute the great body of the profession in the two countries. For these the period is four years in England, and only eight months in the United States. D. R. ought to have known that our comparison did not extend to F.R.C.S.'s of the United States (if there be such a class), and therefore to have placed in comparison the F.R.C.S. period of the English College with the Membership period of the United States, would not only have been a deceptive but an untrue representation of the facts. We must express our surprise that an examined Fellow of the College should commit such a blunder.

Mr. J. W. D. Brown's communication has been received, and will be inserted in an early number.

We regret that we are compelled to postpone the Reports of the Liverpool and Newcastle Pathological Societies until next week.

Reports have been received from Guy's Hospital and King's College Hospital.

Mr. R. Sarell.—The letter from the Paris Medical Society has reached us.

Dr. T. H. Barker.—Application should be made to the publishers, with whom these matters entirely rest.

The contribution of Mr. Samuel Berry shall be inserted, if possible, in our next number.

RECEIVED.—Mr. J. O. Burgess.—Mr. Deane.—The "Yorkshire Gazette."

CORRECTION.—At p. 954 of last number, col. 1, line 17 from top, for "8 per 1000," read "11 per 1000."

Lectures.

COURSE OF LECTURES

ON

DISEASES OF THE HEART.

Delivered at St. Vincent's Hospital during the Session 1849-50.

By O'BRYEN BELLINGHAM, M.D.

Fellow of, and Member of the Court of Examiners of, the Royal College of Surgeons in Ireland, and one of the Medical Officers of the Hospital.

LECTURE XIV. (CONTINUED).

GENERAL SIGNS OF HEART DISEASE.

Indirect or secondary symptoms of heart disease (continued) — Dyspnœa—Starting in alarm from sleep—Cough—Hæmoptysis—Pulmonary apoplexy.

Dyspnœa.

THE respiratory movements, like the motions of the heart, are involuntary, though the former are much more under the influence of the will than the latter: they belong to the class of movements termed "excito-motory" by physiologists. The object of the respiratory process, it is scarcely necessary to say, is to bring the venous blood in contact with atmospheric air, which is accomplished through the medium of the innumerable capillaries that ramify upon the air-cells of the lungs; and the changes which ensue in the blood and in the air take place through the delicate membranous walls of these cells. From the manner in which these parts are arranged, every particle of the blood, in its passage through the capillaries of the lungs, is necessarily exposed to the action of the oxygen of the air; and upon the regularity with which the process is carried on the regularity of the heart's action depends, anything which impedes or interrupts it tending to derange or to disturb the general circulation.

When the respiration and circulation are perfectly tranquil, the respiratory movements are performed almost entirely by the diaphragm, which, contracting in inspiration, enlarges the diameter of the thorax from above downwards, and, relaxing in expiration, returns to its former state. When the respiratory movements are carried on more actively, the thorax is enlarged in all its diameters,—the antero-posterior, lateral, and vertical. When, finally, the respiration becomes difficult and laborious, all the muscles in addition, which receive filaments from the system

of respiratory nerves, are brought into action.

In a state of health the exact amount of venous blood is transmitted by the right ventricle to the pulmonary artery, which can be converted into arterial blood in the lungs; and the exact amount of arterial blood is returned by the pulmonary veins to the left auricle, which will pass freely through the chambers of the left side of the organ. At the same time an amount of atmospheric air is taken into the lungs, at each inspiration, sufficient to convert the blood contained in its capillaries into arterial blood. We have likewise seen that, in a state of health, there is an exact standard or proportion between the number of the pulsations of the heart and the number of respirations in a given period: hence, when the circulation is hurried by exercise, the respiration becomes more frequent in proportion; and, as the circulation becomes again tranquil, the respirations diminish in frequency. There is, therefore, in health, a perfect equilibrium between the circulation and the respiration and if from any cause this equilibrium disturbed, dyspnœa will ensue.

It sometimes happens that the blood is transmitted with too little force by the right ventricle to pass freely through the pulmonary capillaries: more frequently, however, the blood is impeded in these vessels, owing to some obstruction to its passage through the left chambers of the heart. Again, it sometimes happens that the blood is transmitted with increased force, or in greater quantity than natural, by the right ventricle: more frequently, however, the air cannot enter the air-cells of the lungs in sufficient quantity to decarbonize the blood transmitted to these organs. In either case there will be a want of due proportion between the extent of the oxygenating surface and the mass of the blood; the respiration will become hurried, or difficult, or laborious, according to circumstances; the dyspnœa will pass into orthopnœa, which, in extreme cases, may terminate in asphyxia.

Dyspnœa will therefore ensue whenever the pulmonary capillaries contain more blood than can be oxygenated by the air admitted into the air-cells, or whenever too little air can enter the air-cells to oxygenate the blood contained in the pulmonary capillaries. In either case the respirations may be more frequent than natural, or the number of the respirations and of the pulsations of the heart may not bear their normal proportion to one another. Under such circumstances the respiration is no longer an involuntary act, but requires the aid of a number of the voluntary muscles, particularly in inspiration, in order that a

sufficiency of air may be taken in to convert the venous into arterial blood. In extreme cases all the muscles which receive branches from the respiratory nerves,—viz. the facial, the external respiratory nerve, the spinal accessory, the glossopharyngeal, the par-vagus and its laryngeal branches, and the spinal nerves distributed to the muscles of the trunk,—are called into almost convulsive action.

Dyspnœa in its mildest form, when the individual is merely short-winded, or readily put out of breath, or finds a difficulty in ascending stairs, although a frequent attendant upon disease of the heart, is observed in many cases where this organ is not in the least engaged. Indeed, dyspnœa is seldom marked in cardiac disease until the pulmonary tissue and the bronchial mucous membrane become secondarily engaged, and it is then often one of the most distressing symptoms.

Dyspnœa to a considerable extent may, however, exist, and yet the patient will deny its existence, either unconscious of it, or regarding it as too trifling to be mentioned. This is not unfrequently witnessed in the class of patients whom we see in hospital, in whom the dyspnœa has made its approaches so gradually that they have become habituated to it, and regard it as of trifling consequence. This, no doubt, is in some measure due to the parts having had time to adapt themselves to the altered circumstances, and in some measure, also, "to the sensibility being gradually blunted by the circulation of ill-oxygenated blood." Thus, as Dr. Williams* observes, "persons affected with extensive emphysema of the lungs are habituated to an imperfect state of respiration, which is shown by a constant lividity of the lips and cheeks:—such an appearance would be a sign of approaching death in other persons."

The severity of the dyspnœa, both in disease of the heart and lungs, is, in the majority of cases, in proportion to the suddenness with which this symptom has set in: thus in capillary bronchitis, in pneumonia engaging a considerable portion of both lungs, in pleuritis with copious effusion, it is the most prominent symptom. It is likewise so in the acute forms of cardiac disease, as where a large amount of fluid is suddenly effused into the pericardial sac,—the result of pericarditis; or where the circulation through the heart becomes suddenly impeded or obstructed, as occurs in some of those cases of acute endocarditis which prove rapidly fatal.

It sometimes happens that a very advanced stage of valvular disease is accompanied by little or no dyspnœa: such cases

are usually met with among the better classes. In the majority of the cases of this kind which come under treatment in hospital, where the patients are obliged to labour for their bread, often exposed to all the vicissitudes of the weather, and often, at the same time, the victims of intemperance,—more or less dyspnœa is constantly present; and in very aggravated cases, besides the habitual dyspnœa, it occurs in paroxysms of increased intensity, accompanied sometimes by a sense of constriction or suffocation, threatening dissolution, which is truly distressing to witness.

When more or less dyspnœa is constantly present, and yet no symptoms of pulmonary disease can be detected, or there is no other manifest cause for its presence, "we may," Dr. Furnivall* observes, "suspect disease of the heart almost from this symptom alone." In some cases which he met with he says—"This was the only symptom for a long time observable, and it appeared long before the characteristic murmur of diseased mitral valve could be detected."

The diseased states of the heart, of which dyspnœa is a prominent symptom, are—pericarditis, with copious liquid effusion; endocarditis, with obstruction in the orifices or chambers of the heart; dilatation of the ventricles, with thinning of the parietes; hypertrophy of the ventricles in an advanced stage, or a combination of hypertrophy with dilatation; valvular disease, particularly considerable contraction of the orifices of the left side of the heart, or free regurgitation through the mitral orifice; or aneurism of the aorta, compressing the trachea, or large bronchi. Dyspnœa, however, is not limited to cases of organic disease of the heart; it is a frequent symptom of the anæmic or of the plethoric state. In such cases, however, the dyspnœa is not constant, but is experienced on walking quickly, or ascending stairs, or on making any unusual exertion. In the former of these cases the dyspnœa, according to Andral, arises from there being too much air relatively to the quantity of blood to be oxygenated; in the latter, from there being too much blood relatively to the air entering the bronchial tubes.

Patients labouring under valvular disease in an aggravated form, complicated with dilatation of the ventricles, and accompanied by much congestion of the pulmonary tissue, are predisposed to attacks of pneumonia, which aggravate remarkably the habitual dyspnœa, and usually hurry on the disease rapidly to a fatal termination.

Starting in alarm from sleep.—In con-

* Principles of Medicine.

* Lancet, 1846.

nection with dyspnoea, a symptom sometimes observed in cases of heart-disease of long standing is a sudden starting in alarm from sleep, accompanied by a distressing feeling of oppression and violent action of the heart, often following a frightful dream. This symptom, Dr. Willis* observes, is probably connected with impeded circulation through the lungs. "As we fall asleep," he observes, "the respiration becomes considerably slower than it was immediately before: in very deep sleep each respiration is an effort, and is apparently only performed from the increasing urgency of the uneasy sensation that is at once allayed by taking in a new draught of air. The pulse at the same time falls in frequency, and the balance is maintained between the activity of the circulation and that of the respiration. But, with a heart acting faultily, pushing rather more blood, perchance, into the pulmonary artery than it can transmit, or, on the contrary, refusing readily to receive so much as returns to it by the pulmonary veins, the balance between the activity of the circulation and that of the respiratory system is destroyed, accumulation takes place in the lungs, the patient awakens in alarm, and, plying the muscles of respiration more vigorously, shakes off the sense of suffocation that was beginning to be imminent."

Cough.

Cough is not a necessary symptom of cardiac disease; few cases, however, go through all their stages without this symptom being present in a more or less marked degree, particularly if congestion of the lungs ensues. The act of coughing, which consists in a sudden voluntary or involuntary expiratory effort, is almost always the result of some irritation of the mucous membrane lining the larynx, trachea, or its ramifications. The nature of this irritation varies in different cases; thus it may depend upon inflammation of some portion of the mucous membrane which lines the air-passages, in consequence of which the sensibility of the membrane is increased, and its secretions, which are not irritative in a healthy state of the membrane, become so, and occasion cough; or it may arise from the accumulation of the secretion in the air-tubes, by which the free admission of air is interfered with, and cough is excited in order to get rid of it. Again, it sometimes happens that the calibre of the air-tube is narrowed by submucous infiltration, or by a morbid growth pressing upon a bronchial tube, and diminishing its calibre, when the irritation excited gives rise to cough.

When cough arises in diseased states of the heart it may depend upon any of the causes just mentioned; most frequently, however, it arises from the irritation occasioned by the increased quantity of fluid poured out into the air-passages, the amount of which is sometimes considerable, and which, by its simple presence, excites irritation, or, by its quantity or situation, impedes the passage of the air during respiration, and cough is excited in order to get rid of it.

In the early stages of cardiac disease, if cough is present, it is in general due to an accompanying bronchitis. In the advanced stage of certain forms of disease of the organ cough is scarcely ever absent, and it is always associated with more or less dyspnoea. In such cases oedema of the pulmonary tissue is generally present, the congested condition of the lungs being in part relieved by the transudation of the more watery parts of the blood into the air-cells and minute tubes: but this very effort of nature to relieve the congested state of the capillaries of the lungs becomes often the source of considerable distress to the patient; the copious secretion poured out, as it can only be removed by coughing, excites and keeps this up; while, if the secretion from the bronchial mucous membrane is at the same time very profuse, and the patient much debilitated, the expectoration becomes difficult, and not unfrequently the patient dies asphyxiated from this very cause.

The diseased states of the heart, in which cough is most frequently a symptom, are valvular disease of the left side, particularly contraction of the mitral orifice, dilatation of the ventricles and hypertrophy of the same parts; in fact, the same forms of disease in which dyspnoea is observed: indeed, the latter is seldom prominently marked, without cough being likewise troublesome.

The cough at first is usually dry, or accompanied by scanty expectoration,—eventually, when congestion or oedema of the lungs is superadded, it becomes free, the expectoration is copious, and consists frequently of a colourless, watery, or mucous fluid. The cough, too, comes on in paroxysms, and in the advanced stage the fits are sometimes both frequent and prolonged, by which congestion of the lungs is still further increased. Patients in whom the pulmonary circulation is much obstructed, and in whom congestion of the lungs has lasted long, appear likewise to be more subject than others to bronchitis, by which the habitual dyspnoea and cough are considerably aggravated.

It is scarcely necessary to observe, that whenever the trachea, or a large bronchial

tube, is compressed by the growth of an aneurismal or other tumor in the cavity of the thorax, cough is a prominent symptom. In such cases, the sensation first experienced by the patient is usually as if something existed in the air-tubes which he would be relieved by expectorating, and he makes many ineffectual efforts to do so. Afterwards, the act of inspiration or of expiration, or both, are accompanied by peculiar sounds, which in general are sufficiently characteristic, and when once heard can scarcely be mistaken, but upon which it is not necessary to delay here.

Hæmoptysis.

The blood which escapes upon the mucous surface of the air passages, and is expectorated, may have its source either from the bronchial or from the pulmonary vessels; and it may come, either from a ruptured vessel, or it may transude without the rupture of any vessel.

We have already seen how intimately related the functions of the heart are to those of the lungs, and how liable the pulmonary circulation is to be impeded when the valves or orifices of the heart are diseased, and prevent the free passage of the blood through its chambers. We have likewise seen the manner in which the over-distended capillaries of the lungs are relieved by the transudation of the serous portion of the blood, giving rise to œdema of the pulmonary tissue. If the impediment to the passage of the blood becomes still more considerable, the vessels may relieve themselves, by allowing the blood itself to transude, when it may be expectorated; or rupture of a vessel may take place, and the blood be effused into the tissue of the lungs, constituting the state termed pulmonary apoplexy.

Hæmoptysis is a symptom only of the advanced stage of cardiac disease, and is limited to certain forms of it; it is most common in young subjects, and in individuals who at some former period had laboured under acute inflammation of the lining membrane of the organ. It was at one time a common opinion, and is probably still with some, that when hæmoptysis takes place in the progress of cardiac disease, or when pulmonary apoplexy occurs in such cases, they depend upon hypertrophy of the right ventricle, transmitting the blood to the lungs with so much increased force as to cause rupture of the minute vessels, and effusion of blood, either upon the mucous surface, or into the pulmonary tissue. This, however, is not quite a correct view of the subject, because, even though hypertrophy of the right ventricle did exist, the blood would find no difficulty in returning by the pulmonary veins to the

left side of the heart. But hypertrophy of the right ventricle is itself almost always a secondary lesion, and the result of valvular disease at the left side, particularly contraction of the mitral orifice. We have seen that this form of valvular disease is a very frequent cause of pulmonary congestion; and, if hypertrophy of the right side supervenes, as is frequently the case when the contraction of the mitral orifice is considerable, the pulmonary circulation being placed between a strong right ventricle propelling the blood with increased force into the pulmonary artery, and a contracted state of the left auriculo-ventricular orifice, by which the pulmonary veins are prevented from freely pouring their blood into the left auricle, it is not surprising that the blood-vessels should relieve themselves by allowing their contents to transude, or that rupture of a vessel should sometimes take place; particularly if anything occurs to hurry the action of the heart.

Hæmoptysis would be a much more frequent symptom than it is in those cases, if, as the right ventricle became hypertrophied and dilated, the tricuspid orifice preserved its normal dimensions, or became narrowed; but as a general rule, almost, when the cavity of the right ventricle becomes dilated, and its walls hypertrophied, the tricuspid orifice increases in size, by which free regurgitation is permitted into the right auricle: part of the strength of the ventricular systole is thus wasted, and the injurious consequences which might otherwise ensue are prevented.

Hæmoptysis is a more common symptom of pulmonary than of cardiac disease; the source of the hæmorrhage is not the same, however, in the two cases: the appearance of the blood is likewise often somewhat dissimilar, while the circumstances under which the hæmorrhage occurs, and the conditions of the circulation at the time, are different. For instance, the hæmoptysis which occurs in phthisis is of the active form, and arises from determination of blood; the general circulation is quickened, and the hæmorrhage comes (as was first pointed out by Dr. Graves*) from the bronchial vessels. Pure blood is frequently expectorated, which is frothy, and of a bright florid hue, though it is often also in clots, and of a dark colour, if it has lain for any time in the air-tubes: the quantity expectorated is sometimes considerable, and in the intervals the sputa are frequently streaked with blood: finally, this form of hæmoptysis is seldom associated with pulmonary apoplexy.

On the other hand, the hæmoptysis which occurs in the advanced stage of car-

diseased disease is of the passive form, and is the result of venous congestion, not of local determination, while the circulation is not quickened generally. The blood expectorated comes from the pulmonary vessels, and the amount is sometimes considerable. This will, however, in some measure, depend upon whether the hæmorrhage is owing to rupture of a vessel, or depends simply upon the transudation of the blood: in the former case the blood may have a florid hue, or it may present a dark or grumous appearance; in the latter, the blood is frequently intimately mixed with the sputa. Finally, hæmoptysis from this cause is occasionally associated with pulmonary apoplexy.

The diseased conditions of the heart in which hæmoptysis most frequently occurs are:—

1st. Considerable contraction of the mitral orifice.

2d. Dilatation with attenuation of the left ventricle.

3d. Extreme contraction of the aortic orifice.

4th. Hypertrophy with dilatation of the right ventricle. This, however, is almost always a consecutive lesion to valvular disease at the left side of the heart.

Few cases of considerable contraction of the left auriculo-ventricular orifice go through all their stages without the occurrence of some hæmoptysis. It is rare in the regurgitant lesions of the orifices of the left side of the heart, particularly so in aortic regurgitation.

The explanation of the cause of the hæmoptysis in all these cases is pretty nearly the same. Thus, when the mitral orifice is contracted, and the passage of the blood through it is impeded, congestion of the lungs in general sooner or later follows, particularly if the parietes of the right ventricle become hypertrophied: under such circumstances any sudden or continued exertion on the part of the patient, or anything which hurries the heart's action, may give rise to hæmoptysis, the over-distended vessels allowing of the transudation of the blood, or rupture of a vessel ensuing. When, again, the cavity of the left ventricle is dilated, and its parietes are attenuated, the weakened ventricle is unable to propel its contents with sufficient force to pass through the capillaries; the blood accumulates in the left cavities of the heart, the pulmonary veins are unable to empty themselves, congestion of the lungs ensues, followed, as in the preceding case, by hæmoptysis.

Pulmonary apoplexy.—When the blood, in addition to being expectorated, is extravasated in the tissue of the lung, it constitutes, as has been already said, the state

with which we are familiar as pulmonary apoplexy. There is then always rupture of a vessel, and the effused blood may fill the air-cells, or the areolar tissue of the lungs may be infiltrated with this fluid, by which the air-cells of the part are compressed or obliterated, and no longer permit of the entrance of air.

Pulmonary apoplexy, although very generally accompanied by hæmoptysis, may occur without it; and, according to its extent, to the quantity of blood extravasated, and to the amount of lung engaged, it may prove immediately fatal, or only so after a longer or shorter interval, or the patient may recover. The attack may be sudden or otherwise, and the symptoms will vary in intensity according to the circumstances just mentioned. It is usually accompanied by increase of the palpitation and of the dyspnoea, by oppression of the chest, by pain referred to some part of the front of the chest, or to the sides, or shoulders, or by a sensation of heat in the chest, by anxiety, by cough, with more or less hæmoptysis, by paleness of the face if the amount of blood expectorated is considerable, or by injection of the face if it is less, as well as by certain physical signs, upon which it is not necessary to dwell here.

The diseased states of the heart in which pulmonary apoplexy is most likely to supervene are those in which the impediment to the return of the blood to the left side of the heart is greatest: consequently it is most frequently observed in diseased states of the left auriculo-ventricular orifice, particularly in a very contracted state of this orifice. When this morbid condition has followed rapidly upon an attack of acute endocarditis, and when the subject is still young, pulmonary apoplexy, as M. Gendrin* observes, is more liable to occur than when the disease has come on gradually, and when the congested state of the lungs has been in some measure relieved by the escape of the serous portion of the blood, constituting œdema of the lung, or when anasarca of the cellular tissue has supervened.

In addition, M. Gendrin remarks, as free regurgitation through the tricuspid orifice usually occurs in these cases, this tends materially to diminish the injurious effects of congestion upon the lungs, and renders pulmonary hæmorrhage less liable to occur, because, at each systole of the right ventricle, a considerable portion of the blood is propelled backwards into the right auricle, which prevents the pulmonary artery from being over-distended, and diminishes the risk of rupture of a vessel. From M. Gendrin's remarks under this

head, it might be supposed that regurgitation through the tricuspid orifice had been overlooked by preceding writers:—"It has always surprised me (he observes) to find this insufficiency of the valve unnoticed by writers, even by those who have made the diseases of the organ their particular study." When describing the mechanism of the action of the valves, however, we saw that the tricuspid valve permits regurgitation even in a healthy state of the heart; and that a condition of the right auriculo-ventricular valve and orifice which permits a partial reflux of blood into the right auricle, when the ventricle is much distended, or when the passage of the blood through the lungs is temporarily impeded, is a natural provision, which had been noticed so long ago as the time of Hunter,* and has been particularly described by Mr. Adams,† and Mr. King.‡

Original Communications.

OF THE

RISE, PROGRESS, AND VARIOUS TERMINATIONS OF CHRONIC OVARIAN TUMORS.

By EDWARD JOHN TILT, M.D.

Senior Physician to the Paddington Free Dispensary for the Diseases of Women and Children, &c. &c.

AFTER describing the structural appearances of chronic ovarian growths,§ we attempted to discover in what elementary tissues they originate, and the causes which determine their development, so as to enable us to form a correct notion respecting their nature: we must now detail their progress, and become acquainted with the accidents by which this may be marked, in order to be furnished with all the elements of a correct diagnosis, when hereafter we seek to distinguish ovarian tumors one from another, and from tumors of other organs. Unlike the acute ovarian tumors which we have already described, the more chronic growths of the same organs are remarkable for their insidious beginnings and for the length of time which they generally require to arrive at their full growth; and their

development is often unattended by fever, whilst we have seen acute ovaritis excite a degree of fever proportionate to the amount of suppuration occurring in its tissue or in its vicinity.

In following the author in a description of the progress of these tumors, the reader must recal to his recollection the extent and nature of the abdominal and pelvic cavities, in part osseous and inextensible, and in part most elastic and yielding. He must also bear in mind the relative position of the abdominal and pelvic viscera, and particularly that of the organs by which the ovaries are surrounded. The enlarged ovarian tumor may encroach upon all these organs, and it is only by following out these encroachments on every individual organ located in the abdomen and pelvis that we shall be able fully to appreciate these symptoms, and to distinguish chronic ovarian tumors from the diseases of neighbouring organs, with all of which they are daily confounded.

In thus carefully studying the influence of chronic ovarian tumors on the different viscera, we shall attempt to continue what Dr. Bright has so admirably begun in the *Guy's Hospital Reports*; that is to say, a more perfect study of abdominal pathology, a subject of immense importance, since full two-thirds of all the diseases to which we are liable either ultimately attack or soon implicate the abdominal viscera.

When treating of the morbid anatomy of chronic ovarian cysts we were able to class them into—1. Piliiferous; 2. Hydatid; 3. Fibro-serous; 4. Heteramorphous tumors; and 5. Cancerous encysted tumors. But it is useless to make this distinction in the description of the effects of these tumors upon neighbouring organs, because these effects are for the most part mechanical, or the result of inflammation, and independent of their nature. We shall see at a future period how difficult it is to distinguish these varieties, as well as to distinguish from ovarian tumors those which are more rarely developed in the Fallopian tubes, but which have the same symptoms and require the same treatment.

The effect of ovarian tumors we shall generally find is—I. To displace more or less the other viscera. II. To give rise to more or less disturbance of their natural functions. III. To wear and

* Treatise on the Blood.

† Dublin Hospital Reports, vol. iv.

‡ Guy's Hospital Reports, vol. ii.

§ Lancet, vol. ii. 1849.

perforate them when these organs are hollow, so as to evacuate by their channel what cannot be reabsorbed. Besides this common mode of acting on all the abdominal and pelvic viscera, these tumors disturb the functions of other organs to which they are allied by some consentaneous bond of union such as the breasts, on which they cannot possibly exert any other than a nervous influence.

We shall hereafter see that the distinction of the symptoms of ovarian tumors into pelvic and abdominal is not without practical importance; but at present, when investigating the march of these tumors, we shall group together the whole of their effects on the same organs, so as not to mar the unity of the plan by too minute a division of the subject. After having fully inquired into the progress of these tumors in relation to other organs, we shall also see what is the *vital activity* of these growths, what is their *duration*, and what their *termination*.

One of the first, certainly the most important organ with which ovarian growths interfere, is the womb, and we shall have to examine the action of these tumors—

I. On the unimpregnated womb.

II. On the impregnated womb.

1. Action of ovarian tumors on the impregnated womb.

The ovarian tumor at first retains the usual position occupied by the ovary, but when it has attained the size of a hen's egg, if free from inflammatory adhesions, it has a tendency to glide down into the recto-vaginal pouch. As the tumor increases in that recess it pushes before it the posterior wall of the vagina, often obstructing this passage so as to render difficult the introduction of the finger, and still more so the introduction of the male organ. When thus situated the tumor presses on the neck of the bladder by its anterior surface, and on the rectum by its inferior, while it often draws down the fundus uteri with it, so as to produce more or less complete retroversion, which has been noticed by Siebold, Boivin, Seymour, and Burns. It may even raise it above the pubes, and by its continued pressure cause it to become atrophied. Sometimes, however, the tumor insinuates itself into the vesico-vaginal pouch, and in time gives rise to ante version of the womb. It will be easily

understood what peculiarities of its mode of attachment may cause the lateral flexions of the womb which have been sometimes noticed.

But the tumor may be so placed as to press upon the fundus uteri, forcing it down as it grows, and thus determining prolapsus or even proclivencia. This is of rare occurrence, but such cases have been noticed by Meissner, Dugast; and in Dr. Mogerikouski's successful case of ovariectomy it is said that the uterus was forced out of the vagina by the cyst. The patient had two children after the operation.

It is impossible for these displacements to occur without considerably modifying the position and dimensions of the vagina; and we find that it is lengthened, and often drawn to one side, when there is but one tumor, as it has been observed by Montaulieu *fil.*, Laporte (Tom ii. *Mémoire de l'Acad. de Chirurg.*), Voisin (*loc. cit.*); and myself.

In a case cited by Duges, the tumor so pressed upon the vagina as to determine the inflammatory adhesion of its internal surface, and consequent obliteration (?). Of course, this latter accident, and even the uterine displacements we have enumerated, interfere sufficiently with the functions of generation so as in many cases to produce sterility.

When, however, the tumor has so increased as to be ill at ease in the restricted proportions of the pelvis, it imitates the womb, which after the first few months of pregnancy rises above the brim of the pelvis, draws up the womb and therefore the vagina, to which it gives a slanting direction, which is recognisable by the oblique and elevated position of the os tincæ. In such cases the vagina often takes upon itself an infundibuliform appearance. Burns thinks that the vagina is more particularly drawn up and lengthened when both ovaries are affected. Thus it has occurred that the uterus is drawn completely out of the pelvis by an ovarian tumor, the neck of the womb forming a narrow canal of from four to six inches long. In the case observed by Cleghorn the womb was drawn up to the navel.

Dupuytren has several times met with the womb drawn up, so as to run the risk of being pierced by the trocar during the operation for paracentesis performed to remove the contents of an

ovarian cyst; an accident, Voisin relates, as having really occurred to a surgeon of his acquaintance.

One of the most singular cases of lengthening of the womb is quoted by Morgagni (Epis. 45, 12) from Vater, who relates the fact of the neck of the womb being stretched in contrary directions by an enormous swelling of the ovary, and by *prolapsus vaginæ* (?) and this leads us to remark, that the ovarian tumor often rises above the brim of the pelvis without leaving the pelvic cavity, to the walls of which it has become strongly adherent. The solid tumors are particularly liable to become permanently established there, displacing the pelvic viscera, firmly fixing the womb, and even incorporating it in their own substance.

If both ovaries are implicated, inasmuch as they are generally affected successively, and one is less enlarged than the other, the smaller one remains in the pelvis, and its retention is proportionate to the obstacles offered to its ascent by its fellow. It is wedged in between the uterus and rectum, even if there are no adhesions. If we find the above-mentioned irregularity in the uterus and the vagina, and at the same time discover an immovable tumor in the pelvis, which weighs upon the posterior walls of the vagina, and pushes it together with the uterus forwards, it may be assumed, if there are no countervailing symptoms, that both ovaries are diseased.

As the tumors increase, and their contents often have an outward tendency, inflammation may arise between the cyst and some part of the parturient canal. The tumor most frequently voids its contents through the vagina; and we subjoin such instances as the reader will not find in the literature of our own country.

Bluff (Jour. de l'Expérience) relates the case of a woman who by degrees ceased to menstruate, while in the meantime the left ovary, by gradually increasing, had at last attained the size of a man's head, and pressed strongly on the vagina, the womb and right ovary remaining unimpaired. Hectic fever came on, in consequence of which an opening was formed on the left side of the vagina, which had become very painful. The contents of the cyst passed through this opening, and the tumor disappeared. The opening being closed,

menstruation became regular, and the patient's health was restored.

Helman (Siebold's Jour. vol. ii.) relates the occurrence of this termination after an effort to lift a heavy weight: probably inflammation had previously softened the tissues, which burst asunder from intense muscular exertion. Wertenkampff also saw the left ovary attain the size of a man's head, and empty itself through the vagina; the patient was cured, and menstruation returned. Munro observed a similar substance; but the dropsical effusion returned, and terminated by carrying off the patient. Mme. Boivin saw two similar cases; the one was cured, and in the other the disease returned. Hey (Prussian Med. Journ.) was on the point of tapping a woman, when water gushed from the vagina, and flowed for four days: the patient recovered. Burdach treated a woman who, on lifting a heavy weight, burst an ovarian tumor, the fluid of which was evacuated by the vagina. A year and a half after, the dropsy had not returned (Hufeland's Journ. of Prac. Medicine, June 1833). A similar case is published by Forcke (Hanover Annals, 1838). In some cases the liquid seems to have sought for itself a more complicated, although a natural passage, by passing through the Fallopian tubes, the uterus, and the vagina. Blasius (Commentatio de Hydrope ovariorum profuente, Halle, 1834) has collected several cases wherein the contents of the cyst were emptied by the Fallopian tubes into the womb.

Schmucker also says, that in one case, after the sixteenth tapping, the ovary became suddenly extremely painful in one night, and was followed by the discharge of a large quantity of very offensive ichorous matter through the womb, which discharge continued for some days, and then ceased.

Frank (De Cur. Ret.) gives a case where serous matter was discharged until death, by the uterus and vagina, to the extent of one pint per day. The patient died of consumption, and thirty-one pints of fluid were found in the left Fallopian tube. Sir Astley Cooper mentions, also, a case of this description.

And, lastly, Dr. David D. Davis used to narrate a case in his lectures where the discharge of the fluid was brought on through this channel in a country-woman by the jolting of her horse as she rode to market.

CONSIDERATIONS ON THE CLIMATE OF ITALY,

WITH REFERENCE TO THE TREATMENT OF CHRONIC DISEASE.

BY JAMES EDWARD POLLOCK, M.D.,
Licentiate of the College of Physicians, and Medical Resident at Rome from 1842 to 1849.

THE effects which a change of climate is capable of producing on chronic diseases must ever be a matter of great interest to a community like ours, where the delicacy of frame engendered by the pursuit of wealth, or the luxuries which it supplies when attained, are so often and so conveniently sought to be remedied by the complete alteration in climate, habits, and scenery, which is popularly called "change of air." Thus the expediency of obtaining a greater degree of accuracy in the data from which the practical physician is now so frequently called on to form a judgment on the propriety of removal to a southern climate in certain cases of disease, threatened or existing, must have often occurred to those who, from their position, are regarded by the public as the best authorities on such matters. Of the numerous class of English travellers who are met with in almost all countries at the present day, a very large number have obtained the authority of some physician of note at home as a warrant for the efficacy of their experiment in search of health. In our present artificial state of society, where wealth, and the struggles for its attainment, are the too common causes of derangement of health, and the frequent origin of organic disease, the same power fortunately brings with it its antidote, and supplies the means of obtaining a remedy which removes the patient from the influence of a host of exciting causes, and often relieves the physician from the painful task of prescribing remedies whose power is daily counteracted by the pernicious habits of the sufferer, for which business and the requirements of station and society form so ready an excuse. On the other hand, an examination of any average number of these valetudinarians, when arrived at their destined residence abroad, reveals, as might be expected, a vast variety of ailments, and the usual modifications of disease by the accidents of

temperament and constitution, as well as many individuals whose frames will pass a critical examination without offering any symptoms but those of an overworked brain, or the signs of the life-battle in the senate or at the bar, in the pulpit or in medicine; for the characters of which the philosophic physician will seek first not in the tongue, pulse, and organic structures, but in the careworn face of his patient, and in the recognition of which he will be more assisted by Lavater than by any treatise on medicine or doctrines of the schools. But, deducting from the crowd of cases, real or imaginary, all those to whom the mere abandonment of home and its cares is a remedy of power, there will always remain a number of real affections, which the foreign physician will with surprise find grouped in the same locality. A large proportion will be found to be in some stage of phthisis, or in that precarious condition of health which so often precedes the deposit of tubercle in the lung, where a depraved state of nutrition and a lowered condition of the vital powers seems to prepare the ground, as it were, for the seeds of an intractable disease. These cases perhaps more than any other are modified by the temperament and idiosyncrasy of the threatened victim. And we might in many cases forget the kind of course which the disease, when developed, will pursue by noting with care the state of circulation, the facility and degree of perfection of sanguification, and the strength and vitality of the tissues. When declared disease exists we need scarcely say that its varieties and modifications by age, hereditary predisposition, sex, and temperament, are almost endless, and require on the very face of them a various form of remedy, whether that remedy be the mild and sedative in diet, drugs, or air, or the stimulant and bracing furnished from the same sources.

The object of the present remark is merely to call attention to the important fact of great differences existing in the aspects of the disease in question, which should in all cases be taken advantage of by the scientific physician,—differences which so alter the main features of affections bearing the same name, and resulting in similar pathological changes, that, were it not for consistency in classification (a rock on which we so often split), we should be compelled to assign a different nomenclature, as we are forced

to meet them with a widely varying mode of treatment.

To prove that the remedy in question—a removal to a southern climate—is nearly as varied as the affections for which it is recommended, we have only to consult the accumulated observations of scientific visitors and others to the numerous places of resort in France and Italy, which have obtained some character for the curative powers of their climate. That these differences are real, and not imaginary sensations of too nicely observant invalids; any one who has travelled from Paris to Naples by land can testify; especially if he has been unfortunate enough to encounter a "Mistral" at Montpellier, or Hyères in Provence; the "Bis" at Nice, a blast up the Valley of the Arno in Florence, or a "Scirocco" at Rome or Naples. Nay, more: let the everyday air of Nice and Rome be contrasted by any one in health, and the different effects of what are called the "stimulant" and "sedative" will be very perceptible.

Now that our facilities of travelling have been so increased, and information on foreign localities become so general, the English physician declines sending his consumptive patients to encounter the keen breezes of Montpellier in France, or of Geneva from the Alps, and is also well aware of the differences between Rome and Nice; yet many English inscriptions in these places bring painful memories of a time when the medical philanthropist will often bitterly regret when the long journey and the abandonment of home and friends—those alleviations of the last stages of chronic weakness and the foreign grave, how much dreaded by the many!—might have been spared the wretched sufferer. But on these local differences in characters of climate it is not necessary here to dwell much. Let us establish distinctly the two facts, that among those cases for which the physician at home would often recommend removal to a southern climate, there exists an infinite variety, the individual peculiarities of which he would gladly meet by some corresponding characters of climate; and that such climates as the South of Europe offer at least some important differences of which we may take advantage. If we can satisfy ourselves that a remedial action is in any case manifested, we desire to know with the greatest possible accuracy how to

select both the nature and stage of the affection, so that our curative means shall correspond with the indications furnished by a careful observation of our patient, which will, in fact, be only to follow, in the application of climate as a remedy, the same rules which daily guide us in therapeutics; and if, by a like observation of the localities resorted to, we can satisfy ourselves that in any case a positive *nischief* may result from such a removal, we should shun its employment as we would that of depletion, or other lowering treatment, in an already exhausted system.

In elucidation of these points it is a question of no little moment, and one pressed upon us by the light which modern research has thrown on the subject of vital actions, as well as by ethnological investigations, to what extent a continued residence in a climate new to the constitution can alter or modify the *healthy* system. If in our study of the question we regard attentively the physical and moral features exhibited by natives of the soil, we are struck at once by the fact that mere differences of "race" cannot wholly account for the varied physical condition of the inhabitants of countries geographically separated. The effect of governmental institutions bearing on the education, supply of home comforts, and the entire social condition of a people, can do much, even in one or two generations, towards conferring a peculiar recognizable stamp on all classes of a population. Yet there are plainly constitutional varieties in whole nations or districts for which no government or misgovernment can be entirely responsible, and which are attributable to other than even these important elements of physical elevation or depression. From whence arises the hardy enterprise and intrepidity of the Swiss,—the languor approaching to solemnity of the Roman, his impassive, almost sullen aspect, to a northern eye,—or the unceasing yet trifling life-energy of the unresting Neapolitan? The two latter are equally badly governed, equally ignorant and oppressed; but the air which blows across the Bay of Naples is not the sullen vapour which is wafted from surrounding stagnation into the city of the plain. How marked is the progressive increase of energy as the traveller proceeds from Italy to France and Germany, till he reaches that great mixture of the energetic and phlegmatic

temperament found united so happily in his own islands. The authority of travellers of intelligence has no doubt attributed these varieties to "race;" yet climate forms so essential an ingredient in race, that very much must be attributed to its influence, and the writer has been led from observation to believe that all the effects on disease traceable to a southern climate are shown on the healthy northern system in degrees varying with the sensibility of the individual to such external influences.

A great deal has been already written on the subject, and few places of note on the Continent are unfurnished with a treatise by a local English physician, whose dictum is generally a law to his freshly arrived countrymen. It must be confessed that such treatises are generally very worthless to the practitioner at home, being more commonly addressed to the public than to the profession, containing often that species of "popular medicine" for which our countrymen have at this moment so great a mania, and, by indiscriminate praise of the climate or the springs, as the case may be, have not tended to raise us above the level of the vast mass of pretenders to curative powers who are at war with the less attractive, but more calm, observations of science on the cure of disease. To these there exist brilliant exceptions in the works of such men as Sir J. Clark and others, whose remarks are founded on personal observation, and contain impartial comments on climate. Of late, also, we have been furnished with correct tables of temperature and its ranges, of the hygrometrical condition of the atmosphere, of the prevalence of winds, of the influence of geographical aspects of countries, and of various other physical observations which have most important bearings on the frame, both in health and disease; and, without doubt, much more remains to be done in perfecting these records. On these points we do not intend to dwell, but rather to present a view of more practical facts; for, after all, we do not (we should not) select a particular climate for an invalid from mere considerations of temperature, &c. The latter may guide us, and should always have their due weight; but we have long been persuaded that information gathered *only* from these sources is liable to mislead, and has misled, the profession at home. It is

by viewing the various peculiarities of a locality *as a whole* that we shall form a correct judgment beforehand of its eligibility, as it is by watching the after history of its actual effects that we can alone truly test its results on the individuals placed under its influence. In such a view the action of the imponderable agents—heat, light, and electricity,—the variations of atmospheric currents—the presence and degree of moisture, &c.—are to be regarded in connection with other considerations, such as the possible admixture of marsh poisons with the air, and the general influence, moral and physical, of all these agencies together, as evidenced in the health and natural temperaments, as well as in the diseases of the native inhabitants; and to this must be conjoined a study of the climate left, to which the traveller has been, as it were, indigenous, and from which he derives himself many striking peculiarities. We shall thus regard him much as a scientific gardener views the plant of other climes, whose former physical relations he studies with care in regard to its present treatment, which he even makes comparative to them.

Supposing, then, that we are familiar with the general physical facts regarding temperature, winds, electrical and hygrometrical phenomena, which may be obtained from many published tables, the writer proposes to record his observations on the effects of a southern climate on the healthy and diseased system, and thus to contribute something to the after history of cases of which the home physician often loses sight, as well as to elucidate, if possible, the physiological aspect of the questions which arise in connection with the removal of invalids to a foreign country.

It is right to state that the observations are the result of seven years' continuous residence in Italy, each winter being spent in Rome, and that the writer has enjoyed fair opportunities, from private practice, of judging of the effects of the climate of that country.

It will be convenient, before entering on any details of the effects of climate, to consider briefly—first, the class of cases which are most generally so treated, and, secondly, ~~what~~ we propose to ourselves by the ^{present} patient. If we are question general characters of the ^{present} patient.

abroad, and the average success which attends the experiment, we shall be led to the conclusion, that two kinds of sufferers are most exported, and most frequently benefit by the removal. First, those *threatened* with organic disease, principally of the chest; and, secondly, those who, having already undergone some morbid change of structure, have exhibited a degree of power at least of rallying under the injury, nature making an effort to support the general strength, which the physician would gladly and wisely assist by every means in his power. The first is the antecedent to, the latter the confirmed stage of, what we understand commonly as chronic disease. In our present consideration we include the curative attempt of nature as an essential part of the definition of chronic disease, a pathological point of vast importance, and our best guide to treatment of an effective kind, leading its student to an investigation of when and how the reparative attempt is being made, and pointing him to the inquiry, how far he can assist, by extraneous treatment, in the curative effort of the system.

If we analyse the variety of remedies advised in chronic disease by those most called on to prescribe for, and most familiar with such cases, we shall find that an improvement of nutrition, a strengthening of the reparative power by an increased supply of an improved quality of blood, is what is aimed at, and that to this tends the multifarious means so often resorted to; and that, whether attempted by the highly-lauded horse exercise of Sydenham, or by a course of tonics, by any of the innumerable class of so-called "alterative" medicines, or by removal to better air, and improvement in diet, the same object is in view—a bettering of the material by which nature is attempting to elaborate or repair, or wall round with a barrier of low vitality, the injury which, in a weaker hour, she has undergone. In selecting from such a numerous class of remedial agents, the student of the present day will, by observation, be gradually led more and more to abandon a vain search after specifics, and, if he have gathered any hint from the spirit which emanates from those best and highest in the profession, will endeavour to spare his patient many a dose, but rather, by strengthening organs which are plainly awaking to

energy, than by stimulating actions which it is doubtful if he ever can command by drugs, lend a hand to the restoration which nature is attempting. Along with this it is important to remember that slowness, whether to destroy or to repair, is a constant character of chronic disease, and that to depart from this in our efforts is to impede rather than to assist, and has too often converted a natural tardy process into one rapidly destructive to the powers of life itself. If we inquire how the scientific physician has been led to adopt the above idea of treatment, we shall find that it has been founded on the observation of the fact, that in chronic disease a deprivation of the process of nutrition has invariably preceded the lesion of the affected organ, and we can thus perceive with increased force the value of the efforts which would strike at the very root of the affection, in preference to an attempt to obviate some of its more prominent results. It also enables us to see that the two classes into which we have divided the cases usually selected for a change of air have in reality one important feature in common, and mainly important as regards their treatment—that both the cases of threatened disease, and those of resisted established disease, are accompanied by some change in nutrition in the largest meaning of the word, which forms at once the point of departure from a state of health, and furnishes the curative indication, being the obvious field for the exercise of all, or nearly all, the treatment which can be efficacious. With these views it will be a question of first importance what influence climate and particular climates can exert in effecting any curative change on the nutrition? and an inquiry clearly secondary to this, but still of interest, will be made into its palliative effects on symptoms.

To elucidate these points, we propose to examine briefly what are the characters of the climate of the South of Europe, and what its effects on the healthy system as manifested in the temperament of its inhabitants, as well in health as in disease, and, further, to trace the parallel operation of such influences on the healthy and diseased English system; and, shortly, to record a summary of our observations on the varied cases of disease which have fallen under our notice.

ILLUSTRATIONS OF PANCREATIC DISEASE.

By H. FEARNSIDE, M.B. LOND.
Physician to the Preston Dispensary.

THE cases detailed below are chiefly important in a pathological point of view. The first is remarkable for the rarity of the disease of which the patient was the subject; Storck being the only observer hitherto, so far as I am aware, to whom an example of pancreatic hæmorrhage has occurred. The second case is interesting, not only from its bearing upon disease of the pancreas, but also as an instance of a form of heart disease which has lately attracted considerable attention.

Disease of the pancreas has been considered to be less frequent than that of any other large gland in the body; but the correctness of this opinion is somewhat questionable.

The importance of the pancreas in the animal economy is seen in the all but universality of its presence in the vertebrated classes, and its existence even in some invertebrata. Its situation in the body, and the point at which its duct enters the intestine, indicate that its function is to assist in the digestive process; but respecting the precise nature of the office which its secretion serves, much obscurity has prevailed. Even the statements made by different observers, as to the character and composition of the pancreatic fluid, have been contradictory. Some of these discrepancies are accounted for by the fact that, of all the animal fluids, it appears to undergo change most readily; and, in experiments upon animals, its quantity is often increased, and its composition altogether altered, by the inflammation consequent upon the operation.

The results of a more complete and extended series of investigations upon this subject have recently been published by Dr. Charles Bernard,* from which it seems that the secretion is a colourless, limpid, saline, and somewhat viscous fluid, invariably alkaline in reaction, and coagulable by heat and acids; but the material to which it owes this property differs in certain respects from albumen. M. Bernard's researches

tend to prove that the special office of the pancreatic fluid is to effect the digestion of fatty bodies. Until their publication the doctrine generally taught by physiologists was that held (with certain modifications) by Leuret and Lassaigue, Tiedemann and Gmelin—that the bile dissolves the fatty part of the food, or at any rate favours its absorption, by contributing to its minute division. M. Bernard states that, on the admixture of fatty matter with pancreatic fluid, it is resolved into glycerine, margaric, stearic, and oleic acids; whereas saliva, gastric juice, and bile, produce no such effects. This last assertion, however, is denied by Frerichs, who merely admits that pancreatic fluid will form an emulsion with oil.*

As an acquaintance with the functions of organs in their normal state must ever precede the useful study of their deviations from the standard of health, it is to be hoped that these observations may be susceptible of beneficial application to this obscure department of pathology.

Gradual failure of the health for twelve months, with symptoms of deranged digestion; increased intensity of these indications during the last three months of life; paroxysms of acute suffering in the region of the stomach; sudden accession of excruciating pain in the same situation; syncope, vomiting, hiccough, great prostration, and death.
—Great enlargement of the pancreas; signs of inflammation in the body and left extremity of the organ; hæmorrhage into the substance of the right extremity; great dilatation of the stomach.

R. H.—, aged 49 years, a man of middle stature and average conformation, was moribund when seen by me for the first and only time in August 1849. His employment for many years had been that of a farm labourer, and his habits not remarkable for temperance; but he had generally enjoyed good health until within the preceding year. During the period mentioned he had frequently suffered from deep-seated pain in the region of the stomach—occasional sensations of coldness—others, of heat in the same situation—gastrorrhœa, pyrosis, constipation: and

* *Archiv. Génér. de Médecine*, Jan. 1849; vide also *British and Foreign Medico-Chirurgical Review*, April 1849.

* *Wagner's Handwörterbuch der Physiologie*, quoted in *Monthly Journal of Medical Science*, February 1850.

he had never had vomiting; he had lost flesh and colour in some, but not a very striking degree. For the preceding three months the paroxysms of pain had been more severe in character, and more frequent in recurrence, until at length they became almost constant; but they were generally most distressing a few hours after taking food. For some weeks his appetite had failed, and he had complained of chilliness, and pain in the limbs, shoulders, and back, which he ascribed to his having taken cold, as he still remained at his work.

Three days previously to my visit he had been suddenly seized with excruciating pain in the epigastrium: this was followed by faintness and vomiting, and the fluid ejected was described as being of a dark brown colour.

On the following day he became jaundiced; the vomiting continued; the pain abated somewhat; but he began to be harassed by frequent hiccough.

When I saw him his pulse was very small and rapid; his hands and feet were cold, his intelligence perfect; he complained of severe pain in the upper part of the abdomen, which was obviously fuller than natural. On pressure between the ensiform cartilage and the umbilicus, a deeply-seated tumor could be felt, extending chiefly in a transverse direction; the liver did not appear to descend below the margin of the ribs in the right hypochondrium; he had frequent hiccough, which often gave rise to an attempt at vomiting. There was extreme restlessness and jactitation, and he died in a few hours afterwards.

Examination of the body 18 hours after death.—There was some, but not a remarkable degree of emaciation, there being still present a small quantity of fat in the walls of the abdomen. When the abdominal cavity was exposed, the stomach, much enlarged, was seen extending across its upper part, and reaching much farther to the right than natural. On drawing aside the stomach, the tumor which had been felt during life was seen to be formed by the pancreas, increased to at least four times its normal size; some adhesions of a rather firm character existed between it and the posterior surface of the stomach; and the peritoneum in the neighbourhood, both diaphragmatic and parietal, had in several spots lost its transparency, and was thickened by the

deposit upon its surface of exudation-matter, some of which was soft, flocculent, and easily detached, but the greater part was firm and adherent. Implicating the whole of the organ in a certain degree, the increase of size was most striking in its right extremity, which passed deeply into the right lumbar region, carrying with it the duodenum. This portion, of a blackish brown colour, was almost entirely converted into a pulaceous, grumous mass, whose slight coherence was such that it gave way in the attempt to remove it from the body. In the more consistent parts distinct sanguineous coagula were met with, and every trace of the natural tissue of the gland had disappeared. Both the body and left extremity were also profoundly changed in structure: the body was of a dark red colour, mottled with black lines and points; it was very firm and close in texture; and, on a thin slice being broken across, the fracture was short and crisp. In approaching the left extremity, the colour underwent a gradual change, becoming lighter, and the part last mentioned was of a pale yellow hue; it was also close, firm, and uniform in structure, although less so than the body of the organ. Both these portions were strongly adherent to the posterior abdominal walls.

The liver was small, firm, and rather yellow than brown in colour; the biliary ducts contained much bile; the gall-bladder also contained a large quantity of dark bile.

The kidneys were small, contracted, and the cortical tissue less distinct than usual.

The rest of the viscera were healthy.

Progressive loss of strength, flesh, and colour, for two years; symptoms of imperfect digestion and sanguification; development of extreme anaemia; signs of cardiac atrophy; gradual sinking, and death by exhaustion.—Fatty infiltration of pancreas; pulpy softening of spleen; fatty degeneration of the walls of the left ventricle of the heart.

J. H.—, aged 48 years, a rather tall man, of light complexion, and moderate conformation, came under treatment in the autumn of 1849. His occupation was that of a millwright; his habits of late years temperate, but early in life the reverse. Both his parents died at an advanced age. His health had been generally good until two years pre-

viously: about this time his circumstances became less prosperous than they had formerly been, and he was the subject of considerable anxiety of mind. Since the period mentioned he had suffered occasionally from a sense of uneasiness in the epigastrium, at times amounting to actual pain, usually increased after taking food, sometimes immediately, but more frequently after the lapse of two or three hours; occasional vomiting, especially in the morning; profuse flow of saliva; gastrorrhœa, pyrosis, flatulence, loss of appetite, flesh, and colour.

These symptoms had been gradually increasing in severity and constancy; and, during the last twelve months, he had several times been compelled in consequence to discontinue his employment for a week or fortnight, at once; and, for the three months preceding the time of my seeing him, he had been altogether unable to work. When he came under my notice he was much reduced by long suffering: his complexion was remarkably pale; his lips and gums bloodless; his feet and legs œdematous: he complained of extreme debility, and of the existence of a "lingering gnawing pain" in the region of the stomach, not constant, but often brought on by taking food, and especially felt some hours afterwards: he had no vomiting, and had only once been sick during the preceding two months: his tongue was pale and clean; his appetite variable, but not often below its average in health; his bowels were irregular, sometimes confined, but more generally relaxed, and the evacuations often dark in colour, but at other times light and frothy. For some weeks he had experienced almost constant palpitation in the epigastrium, and during the same time he had been distressed by a continual humming or buzzing in the ears: he had also suffered much from frontal headache. On any little exertion his breathing became hurried and embarrassed; he often complained of a sense of oppression about the chest, and sighed frequently, and on several occasions he had shown a tendency to syncope: his skin was cool and dry; his pulse was small, weak, sometimes irregular, and about 80 per minute. On physical examination of his chest, the lungs presented no signs of disease; the impulse of the heart was feeble; and, on percussion, the dull sound eli-

cited over the heart was below its normal extent; a faint blowing murmur accompanied the first sound, and was heard over both the apex and base of the organ, but most distinctly in the latter situation: there was also a want of clearness about the second sound: a very loud, continuous murmur was heard over the veins of the neck.

There was some tenderness on pressure over the epigastrium, and in a lower degree over the whole abdomen, but no well-defined tumor could be distinguished; the liver did not descend much below the margin of the ribs; there was considerable throbbing of the abdominal aorta; and, on auscultation over the præcordia, a distinct bellows murmur was heard with each systole of the heart. The urine was high-coloured, and deposited a copious sediment of lithate of ammonia.

His speech was hesitating, as if he had difficulty in recalling appropriate words, and he complained of dreaming much at night, especially about old days and former scenes.

Progress of the Case.—For a short time he seemed to derive benefit from the use of steel and a general tonic and supporting regimen: but these means afforded him only temporary relief: he gradually sunk, and died in about a month from the time when he was first seen.

Examination of the body, thirty hours after death:—

There was very considerable emaciation, and great and universal pallidity of the body.

The head was not examined.

Thorax.—There were about four ounces of serum in each pleural sac; the lungs were voluminous, somewhat congested inferiorly and posteriorly, but healthy in every other respect. There was a small quantity of fluid in the pericardium; the heart was small, weighing only 7 oz., it was pale in colour, soft and flabby; the lining membrane of both auricles, ventricles, and aorta, were stained of a deep red colour; there were a number of small red granulations, of the size of millet seeds, along the margin of the mitral valve, both laminae of which were of a deep purple hue; there was no thickening nor loss of transparency in the endocardium; the aortic valves were healthy; the walls of the heart in several situations, but the columna carnea of the left ventricle

in particular, presented numerous pale buff-coloured spots, portions of which, on examination under the microscope, were seen to consist almost entirely of fat, and many of the fibres in the adjoining parts presented a granular appearance, and were devoid of the cross striæ. Beneath the lining membrane of the aorta, in several situations, were patches of pale yellow atheromatous matter.

Abdomen.—The intestines generally were dark-coloured externally. The stomach was small; its mucous membrane exceeding small, but not otherwise unhealthy; that of the duodenum, however, especially in the neighbourhood of the stomach, was raised up in points of the size of pins' heads by enlargement of its glandular structure, and in the inferior transverse portion of the duodenum and commencement of the jejunum the membrane was of a dark red colour, and very soft in consistence. The liver was rather small than otherwise, firm, and of a pale brown colour.

The pancreas was rather above the usual size; it was pale in colour, firm in texture, and had undergone a great alteration in structure: on a section it presented a nearly uniform pale yellow surface, greasing the scalpel in a marked degree: scarcely any of the true lobular tissue of the organ could be discerned, the whole being infiltrated with fat.

The spleen was of the usual size, but exceedingly soft, being little more than a capsule containing semi-fluid blood.

The kidneys were small, pale, and loaded with fat internally. The mucous membrane of the colon and rectum was of a dark grey colour.

REMARKS.—As in both of the cases just narrated disease of the pancreas must have been long in progress, it may be useful to indicate what common and characteristic symptoms were afforded by them.

The earliest phenomena noticed were gradual failure of the general health, and faulty digestion; but these symptoms being present in a variety of diseases are of little diagnostic value. *Deep-seated pain in the epigastrium* occurred in both patients, and in both is said to have become aggravated a few hours after taking food. But the importance of this remark is diminished by the signs found after death in one of the cases, of the previous existence of inflammation

of the mucous membrane of the duodenum. *Gastrorrhæa* was present in both cases. Some have supposed that the fluid ejected in this affection is a vitiated secretion of the pancreas; but its existence concurrently with such extensive disease of that organ as was found after death, and must have been going on long before that event, when little or no secretion could be eliminated, is adverse to that opinion, and would rather lead us to conclude that it is simply a flux, the result of hyperæmia of the mucous membrane of the stomach, and analogous to the catarrhs of other mucous membranes.

Ptyalism was made the subject of spontaneous complaint by one of the patients. This is a symptom which has been repeatedly observed in cases of disease of the pancreas, and to which considerable importance has been attached, from some conjectured antagonism or "balancement" between the pancreas and the salivary glands.* In the same case in which the last symptom presented itself, the tongue was invariably *pale and clean*, and the freedom of this organ from morbid coating in cases similar to those under review has been made the subject of former remark. *The appetite* was variable; in the case longest under observation, the quantity of food consumed was generally not below the average of health.

The last case also presented a sign upon which some stress has been laid by Professor Siebert, of Jena,† as evidence of pancreatic disease, when co-existing with other indications,—viz., *abdominal pulsation*. In one of the cases the *action of the bowels* was insufficient, as is stated to be the general rule in these diseases; in the other it was irregular; but in neither case, so far as my observation extended, or I could learn from others, was fatty matter ever present in the evacuations, as noticed by Dr. Bright in certain cases of diseased pancreas.‡ In the case last narrated, the urine was repeatedly examined, both chemically and microscopically, but except in being generally scanty, and abounding in lithate of

* M. Mondiere, in *Archiv. Génér. de Médecine*, t. xii. p. 153; also Dr. Battersby, *Dublin Quarterly Journal of Medical Science*, vol. xxiv.

† *Monthly Journal of Medical Science*, Sept. 1848.

‡ *Pathological and Practical Researches on Diseases of the Stomach, &c.* 3d Edition, p. 387.

ammonia, it did not deviate from the natural state. *Emaciation* and *anæmia*, present in both patients—in one strikingly,—are generally seen in protracted pancreatic disease: in the one respects, as in some others, the last-detailed history shows a resemblance, almost amounting to identity, in symptoms with a case related by Dr. Abercrombie.* In both, the blood-making functions were greatly impaired, as a consequence of which, and loss of tone in the blood-vessels, there occurred throbbing in the arteries of the head and neck, humming in the ears, and abdominal palpitation. In but one of the cases could any humour, or fulness of the epigastrium, be recognised during life.

It may be remarked incidentally, that the thoracic symptoms present in the last case were such as have been frequently observed in fatty degeneration of the heart. The dyspnoea, oppression about the chest, tendency to syncope, feeble impulse of the heart, and small irregular pulse, all give evidence of a weakened condition of the central organ of the circulation. The altered character of the sounds of the heart during life was ascribed to the existing anæmia.

2. From a review of the symptoms met with in these cases, it may be concluded that although none can be stated to be absolutely pathognomonic of disease of the pancreas, yet the union of several affords a very high probability of the existence of a departure from the healthy condition of that organ. In attempting to arrive at a more minute diagnosis, the *general* symptoms and history, with any information derived from a physical examination of the patient, will prove our chief guides. In the case first related the individual had long suffered in a mode which might have led to the opinion that disease of the pancreas existed; then a considerable tumor was found in the situation of that gland: this might have been occasioned by tubercle, cancer, or simple inflammation: the age of the patient, and especially the freedom from pulmonary symptoms, discountenanced the first supposition. More difficulty, however, existed in deciding between the two last, and the absence of any cancerous hue of complexion merely warranted the expression of a probable diagnosis.

The sudden accession of acute pain, syncope, and vomiting, followed by jaundice, indicated the occurrence of some change, producing pressure upon the gall-ducts, and, from the constitutional sympathy, of a probably disruptive character, but the rarity of pancreatic hæmorrhage prevented the idea of its presence being entertained. In the second case, the group of symptoms, leading us to infer the presence of disease of the pancreas, was more complete than in the first patient. Respecting the nature of the affection it might have been allowable to hazard an opinion from the probable existence of fatty degeneration of the heart.

3. In the case first related the pancreas exhibited on post-mortem examination a very striking deviation from the natural condition of the organ. The increase in the volume and density of the body and left extremity was due to a new deposit of matter within its tissue; not in masses, as when this consists of tubercle or cancer, but uniformly diffused throughout its structure. Presenting also none of the other characters of those adventitious growths, it could be referred only to the effusion of exudation matter, the results of inflammation, to the existence of which the state of the peritoneum, and the adhesions to the adjoining parts, abundantly testified. The appearance of the central portion of the gland closely resembled that seen in a case recorded by Mr. Lawrence,* as one of inflammation; in both the pancreas was of a deep, dull-red colour, very firm, and crisp on incision. In the left extremity the disease seemed to have been of more ancient date, and afforded many of the recognised characters of old-standing inflammation. "When the pancreas has been the seat of chronic inflammation, it is said to acquire a great increase in the density of its tissue, which swells, becomes more dry than natural, and of a reddish and whitish-yellow colour."† The head of the pancreas was completely disorganised, and occupied by a mass of grunous blood. Viewed in connection with the state of the other parts of the gland, there can be no hesitation in regarding the hæmorrhage as the result

* Medico-Chir. Trans. vol. xvi.

† Dr. W. Thomson, Library of Medicine, vol. iv. p. 201.

* Med.-Chir. Trans. vol. xviii.

of softening and ulceration produced by inflammation.

In the second case, the whole substance of the gland was infiltrated with fat, a condition which must be distinguished from mere accumulation of fat between the lobules of the organ.* The results of the same vitiated nutrition were also apparent in the fibres of the heart, which presented both the naked-eye, and microscopical characters of fatty degeneration in a marked degree.

4. Respecting the etiology of these forms of disease, nothing very definite or satisfactory can be stated. Both patients were predisposed to their occurrence, by former intemperance in the use of alcoholic liquors; and from the nature of their occupations, one was much exposed to the weather, the other to sudden and frequent changes of temperature. In the subject of the last case, nutrition had suffered from the employment for some time, of an impoverished diet, and the existence of considerable anxiety of mind. But when we attempt to trace further the operation of these causes, granting them sufficient, our light fails us, from our imperfect acquaintance with the nutritive process.

5. It has been supposed that the obscure disease, diabetes, has an intimate connection with imperfect primary, especially duodenal, digestion; and Bonchardat has endeavoured to associate it with disease of the pancreas, and consequent depravation or insufficiency of pancreatic secretion. The cases related above, however, afford no countenance to that opinion. Although, for some time before death, the gland must have been functionally inactive, yet in the case longest under observation the urine showed no change from its natural condition, except an occasionally being scanty, concentrated, and depositing urate of ammonia.

THE DIVISIBILITY OF MATTER.

MANY years ago a curious calculation was made by Dr. Thomson, to show to what degree matter could be divided and be still sensible to the eye. He dissolved a grain of nitrate of lead in 500,000 grains

of water, and passed through the solution a current of sulphuretted hydrogen, when the whole liquid became sensibly discoloured. Now a grain of water may be regarded as being about equal to a drop of that liquid, and a drop may be easily spread out so as to cover a square inch of surface. But, under an ordinary microscope, the millionth of a square inch may be distinguished by the eye. The water, therefore, could be divided into 600,000,000,000 parts. But the lead in a grain of nitrate of lead weighs 0.62 grains; an atom of lead cannot weigh more than 1,310,000,000,000th of a grain; while the atom of sulphur, which in combination with the lead rendered it visible (in the mass?), could not weigh more than 1.2, 013,000,000—that is, the two billionth part of a grain.

But what is a billion, or, rather, what conception can we form of such a quantity? We may say that a billion is a million of millions, and can easily represent it thus—1,000,000,000,000. But a schoolboy's calculation will show how entirely the mind is incapable of conceiving such numbers. If a person were able to count at the rate of 200 in a minute, and to work without intermission twelve hours in the day, he would take to count a billion 6,944,944 days, or 19,025 years 319 days. But this may be nothing to the division of matter. There are living creatures so minute, that a hundred millions of them may be comprehended in the space of a cubic inch. But these creatures, until they are lost to the sense of sight, aided by the most powerful instruments, are seen to possess organs fitted for collecting their food, and even capturing their prey. They are therefore supplied with organs, and these organs consist of tissues nourished by circulating fluids, which circulating fluids must consist of parts or atoms, if we please so to term them. In reckoning the size of such atoms we must speak not of billions, but perchance of billions of billions. And what is a billion of billions? The number is a quadrillion, and can be easily represented thus—1,000,000,000,000,000,000,000,000; and the same schoolboy's calculation may be employed to show, that to count a quadrillion, at the rate of 200 in the minute, would require all the inhabitants of the globe, supposing them to be a thousand millions, to count incessantly for 19,025,875 years, or for more than 3000 times the period for which the human race has been supposed to be in existence.—*Love's Inquiry into the Simple Bodies of Chemistry.*

MEDICAL GAZETTE.

FRIDAY, DECEMBER 6, 1850.

IN the remarks on the SEPARATE SYSTEM of imprisonment published in our last number, it was shown by the statistical records of the Pentonville Prison, that attacks of Insanity are more prevalent among criminals committed for short periods of imprisonment, than among those who are confined for long periods, whether the comparison of numbers be made with the daily population of the prison, or with the aggregate number of prisoners admitted within the walls; and also that these attacks are more frequent during the earlier than the later periods of long terms of imprisonment.

Results so unexpected as these, and drawn from facts which prove to demonstration the correctness of the opinion given by Dr. Rees and other witnesses, naturally compel us to look for an explanation. This is given by Mr. Burt, whose views we find in accordance with what has been observed of the laws of mental disease.

This gentleman was formerly Chaplain to the Hanwell Lunatic Asylum; he has therefore had excellent opportunities of observing the phenomena of the mind under disease, in addition to his being by education and by profession acquainted with its condition in health. For these reasons his opinions are of great importance in this inquiry. We shall here quote Mr. Burt's explanation of the facts which have fallen under his own observation:—

"It is one of the few known laws of mental disease," observes Mr. Burt, "that transition from one state of moral feeling to an opposite extreme are marked as critical to reason. In accordance with this law, a change of religion is attended with risk to the mind when there is any tendency to

insanity. In the case of grief the facts are notorious. Men inured to suffering will bear it without much danger to reason. It is the sudden inroad to misfortune which overwhelms and destroys the mind, or which calls forth too violent an effort of resistance. That excessive effort will be followed by a prostration of the moral energies; and derangements will sometimes supervene, or the mind be left in the power of the slightest disturbing causes, until it is rallied under new invigorating influences. And certainly it is somewhat remarkable, that of the only two cases of insanity which have occurred at Pentonville beyond the twelve months, one was produced by too sudden a return to association. At once, without having been forewarned, the prisoner found himself among one hundred others in unrestricted intercourse.

The opinion of Mr. Burt, as to the existence of danger to the mind under the separate system, and of the means whereby to counteract that danger, appear to us satisfactory, and it receives confirmation from the fact which he states, that during the last two or three years, in which period the mental affections have increased two or threefold, there has been a diminution of the sustaining moral influences generally, in very nearly the same proportion.

It is to be regretted that more direct and explicit evidence was not elicited by the Committee from Dr. Rees and the Medical Commissioners. The latter were not even examined. If these gentlemen had been submitted to as close an examination as Mr. Burt, we do not doubt that much interesting and important information of a similar tendency would have been elicited.

As it is, we learn, from the concurrent testimony of many witnesses, that the separate system is safe up to a certain term, although they differ as to the precise limit; and we have the results of the experiment carried out at Pentonville, leading to the conclusion that long periods are less injurious to mental health than short periods. It has been

shown that the whole danger to the mind is either exhausted before the first twelvemonth of confinement, or beyond that period it is neutralised by the accumulating moral influences of the earlier period. That the mental affections are not traceable to separation alone, is shown from the fact, that when separation was most rigorously carried out, the proportionate number of cases of insanity at Pentonville was not greater than in prison populations generally, and that since the rigour of separation has been relaxed the cases of insanity

have increased. The evidence of Mr. Burt shows also that the number of cases of mania bear a direct ratio to the number of new prisoners admitted, and an inverse ratio to the number of old prisoners detained in the prison. In short, the cases of mental disease have been observed to undergo a regular diminution in proportion as the term of imprisonment was prolonged, and the moral elements more strictly applied.

As a further illustration of this subject, we subjoin a few tables extracted from the Report of the Committee:—

TABLE I.—*Total Number of Cases of Mental Disease for the Four Years during which the Prison has been open, with the Period of Imprisonment at which the Attack of Insanity took place.*

The following table will exhibit the corresponding statistics for two periods; one in which the prison contained the

greatest number of prisoners for terms exceeding 12 months, and in many cases ranging to 22 and 23 months, and

CONCLUSIONS OF THE PARLIAMENTARY COMMITTEE RESPECTING IT. 975

upwards, one in which it has contained the greatest number for periods not exceeding twelve months. The first period will embrace four years—namely, 1844-5-6-7. The second period will embrace three years and a half—namely, 1843, 1848-9, and the expired five months and a half of 1850. Removals on medical grounds have not been included

among casualties, to which they do not properly belong. But their relative numbers during the two periods have an important bearing upon the question, inasmuch as they contribute to reduce, in proportion to their numbers, the number of actual casualties.

The returns for those two periods will then be—

PERIODS.	Average daily population.	Deaths.	Medical Pardons.	Suicides.	Insane.	Delusions.	Totals.	Medical Removals.
Four years of long terms, viz. 1844-5-6-7	445	11	16	—	3	10	40	9
Three years and a half of short terms, viz. 1843, 1848-9, 1850, actual numbers	447	11	15	3	14	12	55	51
Ditto, ditto, proportional numbers	447	12·7	17·14	3*	16	13·7	62·7*	58·28

The first year having been a period of rigid discipline, it may be well to exhibit the results when that year is omitted. The sum of the statistics of the four years, 1844-5-6-7, will represent the results of the original system for long terms and rigid discipline. The

corresponding totals for the last two years and a half will represent the results of the altered system, during which the term has been reduced and the discipline relaxed, for the purpose of preserving the mental and bodily health.

PERIODS.	Average daily population.	Deaths.	Medical Pardons.	Suicides.	Insane.	Delusions.	Totals.	Medical Removals.
Four years of long terms and rigid discipline	445	11	16	—	3	10	40	9
Two years and a half of short terms and relaxed discipline actual numbers	486	9	12	3	12	7	43	36
Ditto, ditto, proportional numbers†	486	14·4	19·2	3†	19·2	11·2	67	49·6

* No proportional increase is taken under the head of suicides.

† The difference in the population is not estimated.

* No proportional increase is estimated under the head of suicides. If it were, the casualties would

"If we exclude insanity and delusions, and limit the comparison to the mortality, then it will be found that the average annual mortality during the four years of long terms was to the daily population, in actual deaths, 6·18 per 1000; during the three years and a half of short terms, 7·67; during the last two years and a half of both short terms and relaxed discipline, 8·23 per 1000. If we take the whole five years during which the original system prevailed, the average in actual deaths was 5·8 per 1000; but during the last two years and a half we have seen that it has been 8·23.

"Thus there has been an excess of mortality during the years of short terms above those of long terms in the ratio of 6·18 : 7·67, and the increase in the average mortality during the two last years and a half, above the first five years of the original system, has been from 5·8 to 8·23 per 1000. The ratio of medical pardons to the daily population has not much varied. During the last five years it was as the ratio of 8·9 to 1000; during the last two years and a half as 9·05 : 1000."

"If suicides were included in these estimates the results would be even more adverse to the validity of the avowed reason for curtailing the term from 18 months to 12. The returns would then be—

Five years of the original system,
average mortality 5·8

Two years and a half of the altered system, average mortality 13·37

"But the suicides are not included. Upon moral grounds far greater weight attaches, and no doubt will attach, to these disastrous cases, than would be correctly represented by their numerical value. They stand by themselves. During the first five years in which the prison was opened not one case occurred. Since the recent changes in the system, in two years and a half, there have occurred three.

"These naked facts appear more than sufficient to annihilate the argument for reducing the term of separate imprisonment from 18 months to 12 on the ground of increased risk to the mental health during the protracted period."*

It is apparent from all that has pre-

ceded that various influences must conspire before reason will be entirely overthrown under any system of prison discipline. These are to be found in previous habits and course of life, personal character, the greater or less amount of religious and secular instruction that is afforded, the character of associates, and the extent to which association is permitted—all or most of these conditions contribute to the production of insanity among prisoners. Their separation from each other withdraws the vicious and admits the alleviating influences: it favours reformation; and, by favouring reformation, soothes the mind, removing the injurious effects of evil passions on the mind, and thereby acting beneficially on the mental health; and, as body and mind exert mutual influences on each other, it must also tend to diminish the bodily injury. Whatever tendency, then, there may be in prison discipline generally to produce insanity, is counteracted under the separate system, when its educational and reformatory elements are fully brought into play. This is shown by the actual increase of insanity as concurrent with the decrease of moral and religious instruction in Pentonville.

"What to do with our convicts" has always perplexed the British Government: it has ever been felt in England that it was undesirable to return so much vice and such elements of discord loose upon the dense populations of our towns, there to increase the amount of crime, or to foment rebellions, as in France. The recommendations of successive commissions have all encountered obstacles in reconciling with the rights of colonists the protection of society and the claims of justice. One of the most formidable difficulties recently encountered has been the opinion that we have already alluded to, of the injuriousness of the separate system to body and mind. This opinion has been

* See Mr. Burt's supplementary letter in the Appendix to the Report of the Select Committee of the House of Commons.

fostered by medical men on insufficient grounds, has been echoed in Parliament, and has thus, as it is now demonstrated by facts, impeded the progress of the best interests of society in the safe disposal of criminals. We trust, however, that the evidence contained in the Report, which we have here fully examined, will disabuse the public and professional mind on the subject, and permit a free and full trial of the system, for the removal of any doubt which may remain in the minds of those who have neither the time nor inclination to examine statistical documents. For ourselves, we may remark that the evidence supplied by this valuable and elaborate Report is satisfactory and conclusive. The facts stated by competent observers, who cannot be suspected of an intention to deceive the public, leave no room for reasonable doubt that *the separate system may be safely carried out without incurring greater risk to bodily and mental health than is inseparable from imprisonment under any conditions whatever.*

It is, however, a remarkable fact that, despite these proofs of the superiority and comparative safety of the separate system, even for long periods of confinement, the Parliamentary Committee have come to the following conclusion:—

"That separate imprisonment ought to be applied to prisoners under long sentences, during the earlier period of their imprisonment; but this Committee does not recommend that it should, in ordinary cases, be enforced for a longer period than twelve months."

VELOCITY OF THE GALVANIC CURRENT IN THE ELECTRIC TELEGRAPH.

It was stated by the Earl of Rosse, at the recent meeting of the Royal Society, that some experiments had been recently made in France to determine the velocity of the galvanic current in the electric telegraph, and the result was that this velocity had been greatly overrated. It has been found not to exceed a rate of from 11,000 to 23,000 miles in a second of time.

Rebiews.

The Surgeon's Vade-mecum. By ROBERT DRUITT, F.R.C.S. 5th edition. 8vo. pp. 600. London: Renshaw, and Churchill. 1850.

WHEN a medical work has reached its fifth edition, it is merely necessary to make the announcement of its publication. Mr. Drutt's manual is a well-known student's companion; and it has, we believe, had a larger sale than any work of its class. It is a neat compendium of surgical information, not intended or fitted to take the place of larger treatises, but still well adapted to guide the student to a sound knowledge of the rudiments of surgical science and practice. The present edition has been carefully revised; it has attached to it a well-written chapter on the use of chloroform and other anæsthetics in surgery, and it is profusely illustrated by numerous well-executed wood-engravings. We have no doubt that the appearance of this new edition will be acceptable to the greater number of students who have just commenced their attendance on practice and lectures.

Atalektasis Pulmonum; or, Closure of the Air cells of the Lungs in Children.

By GEORGE A. REES, M.D., Lond. Pamphlet, 8vo. pp. 42. London: Highley. 1850

THE description here given of a form of disease until recently unnoticed, is clear and full. Dr. Rees was one of the first to draw the attention of the profession in England to the morbid state of the lungs known as atalektasis; and, from the attention which he has given to this subject, his opinions thereon are trustworthy. The disease is distinct from pneumonia, according to Dr. Rees, although by some it has been regarded as that affection modified by the peculiar state of the lung before and immediately after birth.

The symptoms enumerated by the author as characterising or occurring with atalektasis, are, altered movement of the ribs on respiration, laryngismus stridulus, cough, dyspnoea, emaciation, palpitation, cyanosis, and deformity of the chest.

Dr. Rees's remarks on the diagnosis, prognosis, morbid anatomy, treatment, and appended cases, are brief but good. The entire pamphlet constitutes an excellent practical monograph.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, Nov. 26, 1850.

Dr. TODD, M.D., F.R.S., TREASURER, in the Chair.

A Case of Softening of the Spinal Marrow in a Boy affected with Chorea. By ROBERT NAJENNE, M.D., Physician to St. George's Hospital.

A BOY, aged 17, was admitted into St. George's Hospital, on the 27th of June last, with symptoms of acute rheumatism, and presenting at the same time well-marked symptoms of chorea. A mitral systolic murmur could be heard. The boy had suffered from previous attacks of rheumatism since the age of twelve, but his friends had never seen him "in this way" before. The last attack of rheumatism was about Christmas, 1849. During five weeks before he came to the hospital convulsive motions of the hands had been observed. During the last two weeks he had stuttered much, and frequently contorted his mouth. Five days before admission he had been to market in a cart; complained much of the jolting, and the next day was unable to leave his bed. He did not attempt to walk afterwards, and he was said to have had a fit on the morning of the 24th.

He was somewhat relieved by the treatment employed during the first day or two; he then became worse, more restless, delirious, feebler, and violently convulsed. For two days he passed his motions under him. Some hours before his death the convulsive movements ceased, and he became comatose.

The body was examined 12 hours after death. There was congestion of the veins of the spinal canal, and of the veins and sinuses within the cranium. About an inch of the *entire thickness* of the spinal cord, opposite the third and fourth dorsal vertebrae, was *white, softened, almost diffluent*, the rest of the cord being in its natural state. The brain was of firm consistence and injected with blood. The pericardium adherent; the mitral valve fringed with small vegetations; the lungs congested.

The author remarks upon the points of interest of the case—chorea associated with acute rheumatism, and palsy of the lower extremities depending upon softening of the spinal marrow. He refers

to four cases on record where softening of the spinal marrow existed in persons who had been affected with chorea. He does not consider there is any reason for supposing that in these cases the softening of the spinal marrow was the cause of the chorea. His observation of this disease would deter him from connecting it with disease of the brain or spinal cord. He believes a careful study of the phenomena of the disease during life to be the best means of gaining a truer insight into its nature than we are possessed of at present. He refers to three other fatal cases of chorea which have been observed by him in the wards of St. George's Hospital. One occurred in his own practice, and the other two were patients of Dr. Macleod.

He concludes by remarking, that the curious fact of the existence of sensation, and the transmission of nervous impressions to the palsied muscles of the lower extremities, although the spinal marrow had undergone the change of structure above described, shows that there is yet much for us to learn respecting its functions.

PATHOLOGICAL SOCIETY OF LONDON.

DR. LATHAM, PRESIDENT.

November 5, 1850.

DR. QUAIN exhibited a

Specimen of Fibrous and Fatty Degeneration of the Heart, with the following History.

LADY H—, æt. 58, on rising from bed, on the morning of Oct. 21st, went to the night chair for the purpose of emptying her bladder, then laid down again, and died immediately.

When about thirty years of age she went to India, where she remained fourteen years without any serious illness or inconvenience, and returned to this country some fifteen years ago. She enjoyed good health, save that she complained of headache occasionally, until about seven years ago, when, in her 51st year, the menstrual functions being still regularly performed, she had an apoplectic seizure one evening after returning from a concert. This caused a confusion of intellect and a loss of speech, which lasted for eight or nine days, but no general paralysis of sensation or motion. About eighteen months after she had a second, but a less severe attack, followed by slight weakness of the right upper and lower extremities. Within a similar period she had a third attack

this more resembled the first. She was then in her 54th year, and the menstrual functions began to be irregularly performed. Each attack was treated on the usual antiphlogistic plan, with mercury, and it was remarked that she bore bleeding badly. Soon after the last attack, that is, four years ago, she began to complain of shortness of breathing on exertion. This and the partial paralysis interfered with her exercise, and she became stouter. She continued pretty well until October 1849, when she was one night seized with a most distressing attack of difficult breathing, which lasted about five hours, and was relieved by ether and ammonia. She had no return of the distress, and did well, with the exception of an attack of common bronchitis in February last, until the commencement of September last, when being at Tunbridge Wells she had several attacks, at intervals of two or three nights, of the same difficulty of breathing. For three of these attacks she was rather freely bled. As she still continued very ill she came to town, and I saw her soon after, in consultation with Mr. J. C. Langmore. She was in bed, suffering from a sense of faintness or exhaustion consequent on a distressing attack during the night. These attacks generally came on about two o'clock in the morning, and were of a very alarming character. The extremities and face became cold and livid, the pulse extremely feeble and irregular, and the sense of impending suffocation most urgent. A severe pain in the region of the heart and across the chest came on as the sense of suffocation became less. The pulse was 68, and compressible; it was generally about 60. She was free from giddiness and noise in the ears. She slept well, except when disturbed by these attacks, and was not subject to faintness. She complained of slight pain in the region of the liver, and the motions were pale and lumpy. Mr. Langmore described the urine to be healthy. The heart's impulse was weak, but the dulness in this region was more extended than natural. The first sound was remarkably low and prolonged, the second clear, and hard over a considerable extent of the upper part of the chest. There was no murmur. Some slight sonorous rhonchus was heard in the back. Considering the age, conformation, and sedentary habits of this lady, and also the characters of the symptoms, for which, in the physical signs, no other explanation could be found, the conviction was, that the disease was fatty degeneration of the heart to a moderate extent,—an opinion strengthened by the presence of an *arcus senilis*. The result justified this opinion. She died in about five weeks after my first seeing her.

The treatment consisted of mild mercurials, with taraxacum and aperients; alkalies, with bitter tonics, and a few leeches to the region of the heart, to be followed by iron and antispasmodics during the paroxysms, which produced very beneficial effects. The fits became much less frequent and severe before her death.

Post-mortem.—The body and viscera generally covered with much fat. The calvarium was thick, firmly adherent, and deeply marked inside by vessels. There was more serum than usual in the cavity of the arachnoid and ventricles. On slicing the brain, the remains of the causes of the three apoplectic seizures were found: one, a small spot, the size of a pea, situated in the fore part of the left hemisphere, towards the base, was composed of a transparent greyish substance, like cellular tissue, infiltrated with serum. In each corpus striatum, towards its upper part, was found an orange-coloured spot, about the size of a haricot bean, soft, and in the left having somewhat of a cystic appearance. The white fibres were here broken up and distorted. The arteries of the base were studded with atheromatous or fatty matter.

The lungs healthy. The heart presented rather more fat than usual on the surface, and might weigh about 14 oz. The anterior branch of the left coronary artery was extremely ossified. The right auricle was dilated, thickened, and filled with dark blood. The right ventricle not dilated, but its walls thickened. Their tissue appeared healthy. The left auricle and ventricle were contracted, and nearly empty. The wall of the left ventricle, at its thickest part, measured thirteen lines. The valves healthy. The muscular substance of the septum towards the apex, and the wall of the left ventricle towards the anterior surface of the heart, presented the pale buff colour of fatty degeneration, which passed into and contrasted with the healthy flesh colour of other parts of the heart. A species of ecchymosis, scarcely amounting to hemorrhage, appeared in the diseased part of the wall of the left ventricle. Under the microscope the usual characters of fatty degeneration were found; but there existed also a large quantity of a fibrous texture mixed with the fatty degeneration.

The liver was enlarged, lobulated, hard, and moderately granular. Both kidneys rough and granular, one being larger than natural, the other smaller.

The importance and the possibility of recognising this disease during life was pointed out, even when not very considerable. The treatment, which seemed to a certain extent to have controlled the disease, was referred to, and allusion made to the relation which existed between the

ossification of the coronary artery and the portion of heart affected; showing clearly that the degeneration was due to impaired nutrition.

Nov. 19, 1850.

MR. PRESCOTT HEWETT presented two specimens of

Aneurism of the Mitral Valve.

and a third specimen, in which the appearances so exactly resembled this affection that they were at first mistaken for it.

In the first preparation two well-marked aneurismal pouches existed in the anterior flap of the valve: the larger pouch, of the size of a filbert, was situated close to the attachments of the chordæ tendinæ, and formed a projection into the left auricle; the smaller one, situated a little higher up, presented a jagged opening, which measured four lines in its greater diameter, and two in its lesser. The pouch itself, of a vermiform appearance, and six lines in length, projected also in the left auricle. The internal membrane of the ventricle was perfectly continuous with that lining these pouches, both of which still presented some remnants of coagula. The apices of both aneurisms had been destroyed, having apparently been cut off. In this case the middle aortic valve presented a large ulcerated opening, the margins of which were covered by long soft vegetations; the other valves were somewhat thickened, as well as the root of the aorta, by atheromatous deposit.

In the second preparation the aneurismal pouches were much smaller, but still well-marked. Two in number, they were situated in the anterior flap of the mitral valve, nearer to the aortic opening: they were partly covered with the remnants of coagula, and projected slightly into the auricle. The mitral and aortic valves were covered with long and very soft vegetations.

In presenting these preparations, Mr. P. Hewett regretted that he had no notes of the history of the cases: having been requested by Dr. Peacock, he had brought them forward, as they were well-marked specimens of an affection which was considered as somewhat rare; but he added that, in addition to the cases now before the Society, he had met with four or five others of a similar nature.

In the third preparation—the only one of the kind which had fallen under Mr. P. Hewett's notice—the anterior flap of the mitral valve presented, towards the centre of its ventricular surface, an opening of the size of a pea, with perfectly round margins, leading into a cavity, which at first appeared to be that of a small aneurismal pouch, projecting into the auricle. On

further examination, however, these appearances were found to be produced by a coagulum of blood, which had become adherent to the margin of the opening in the valve; while in the centre of this coagulum there was a small cavity, occupying nearly its whole length. One side of the coagulum was easily detached from the opening, and the true nature of the appearances was at once made evident. The mitral valve was otherwise quite healthy. The heart itself was dilated in all its cavities, and its muscular structure, much atrophied, was flaccid, and easily lacerated. This preparation had been taken from an elderly gentleman, who died of acute inflammation of the membranes of the brain, and had never presented any heart symptoms.

Dr. RISDON BENNETT exhibited (for Mr. Middleton) a specimen of

Carcinoma of the Lung.

A person, æt. 27, had an acute attack of pleurisy in October 1847, which yielded readily to treatment. In March 1848 he was under treatment for secondary symptoms. The following year, in April, he had a second severe attack of acute pleurisy, from which he recovered in about five weeks.

Dec. 1st.—He was suffering from cough, expectoration, night sweats, and emaciation. There was dulness on percussion at the upper part of the left lung, and but little air entered that organ. There appeared every indication of solid deposit taking place: this spread downwards so rapidly, that on the 16th January (six weeks afterwards) it was pronounced to be effusion into the pleura,—so perfectly dull now was every part of the left chest. The expectoration soon ceased while taking cod-liver oil. On the 9th February the diagnosis was supported by a second opinion; and he was treated more actively, but the disease remained stationary: his general health improved, but the complete dulness remained, with absence of respiratory murmur. After being five months in bed, on the 7th May he left town: his appetite improved; he gained flesh; and, in a short time, could walk three or four miles. He returned in August, without any alteration in his chest symptoms, but complaining of a tumor, about the size of a walnut, anterior to the left ear, attended with considerable pain, and two smaller ones on the left side of the heart; they were of a malignant nature, and quickly increased in size; the pain in them became distressing, preventing sleep: he had two or three attacks of loss of consciousness, and was for a time imbecile. At the beginning of November he was expectorating copiously an offensive

matter which rendered the room almost unbearable. There was no doubt gangrene had taken place. He died on the 14th.

Examination.—The right side presented adhesive bands between the surfaces of the pleura, allowing, however, free play to the lung: its upper lobes were emphysematous, but otherwise healthy; the lower one was affected by gangrene. The left lung was connected by firm adhesions to the walls of the chest: the whole lung was solidified, the upper third forming one solid mass of malignant disease, pressing upon all the large blood-vessels, and obliterating the left bronchial tube within an inch and a half of its origin. There was also an enlarged bronchial gland at the bifurcation of the trachea, containing calcareous matter. There was no fluid in the cavity of the pleura.

LIVERPOOL MEDICAL AND PATHOLOGICAL SOCIETY.

November 1850.

Tetanus in an Infant. BY DR. NEVINS.

THIS case occurred in a negro child, about fifteen months old. It awoke in the night, crying, and complaining of pain in the abdomen, which was supposed by the nurse to be colic, and excited no attention. In the morning the feet were rigid and swollen, the great toes were drawn under the adjoining ones, and the soles were hard and tense. The knees were bent, and the fingers were rigidly contracted, the thumbs being drawn into the palms. There was a frequent slight spasmodic movement of the under eyelids, with the exception of which the head was unaffected. The child protruded its tongue when ordered to do so, and there was no curvature of the spine, either backwards or forwards. The flexor muscles of the extremities seemed alone to be affected, and pain was excited by any attempt to straighten them, but the child did not cry when left at rest.

He had had a slight bowel complaint for a week previously, but had not been troubled with worms, nor exposed to cold, nor to insufficient ventilation. I could not discover that he had had any accident; and the nurse said he was quite well, except the diarrhoea, until he awoke in the night, crying. I find, however, on further inquiry, that he had complained of pain in walking for nearly a week; but this was attributed to his shoes having been too small; and a larger pair had been ordered.

On percussing the spine, there was some degree of tenderness over the two lower cervical and one or two upper dorsal ver-

tebrae, but not in any other part. There was no febrile excitement.

Treatment.—He was kept completely under the influence of chloroform above a quarter of an hour without the slightest effect, the rigidity continuing unabated. Three leeches were then ordered to be applied to the tender part of the spine, and a poultice afterwards. He was immersed in a hot bath, gradually raised in temperature, for above half an hour, and took *two minims of laudanum*, and four of spirit of sulphuric ether, *every hour*. In the evening the twitching of the eyelids had slightly increased; he had sweated profusely, and dozed at intervals, but the rigidity was not at all diminished.

Three leeches were applied to the occiput, and his head was shaved and kept cold.

Next day he was still free from pain, and intelligent; but the rigidity was not at all diminished. He showed no signs of being under the influence of opium, though he had taken about *forty minims* of the tincture. The ether had evidently produced no benefit, and the rigidity was too constant to arise from mere spasmodic contraction. The pulse was feeble, and further leeching did not appear indicated by the tenderness of the spine, but a blister was applied along its whole course. He took *four minims of laudanum*, and twenty of antimonial wine, *every hour*, with the sixth of a grain of calomel; and milk diet was given.

In the evening there was little or no amendment, but he was not worse. As there seemed to be a possibility that it might be owing to the irritation of worms, a turpentine clyster was administered; the other remedies being continued hourly.

Next day the rigidity had much abated; there were no worms in the evacuations; no signs of narcotism, though he had taken *two drachms of laudanum* in *two days*; he was not sick, and was still intelligent; the motion of the eyelids was very trifling, the blister was very sore. It was ordered to be poulticed; and the opium, antimony, and calomel were to be given every hour and a half.

The next day there was continued improvement, and the remedies were given every two hours; but the following day he was worse. The rigidity had so far abated that the feet were soft, and all the fingers could be straightened without difficulty; those of one hand remained straight, but the other contracted on removing the band. he sat up in bed, and played with one hand. To day, however, not do this. though not bowels were to this circ

off. The calomel and antimony were therefore discontinued, but the laudanum, in four-minim doses, was given every hour for a few times, and then every two hours. The opinion formed seemed to be correct; for, as the bowels became tranquil the rigidity again abated, and from that time his improvement has been steady. His hands are open, and his feet soft, and the toes pliable. He can move his legs, as in walking, but can not yet (ten days after the commencement) bear his own weight. His muscles are all soft and moveable, and he takes his food and chatters as usual. All treatment is for the present discontinued, and there appears every probability of entire recovery in a few days.

About a week after this report the child was thoughtlessly taken out of the house, the day being cold, and all his symptoms returned, though in a slighter degree than before. Opium, and small doses of calomel, were ordered, and the child was clothed in flannel from head to foot. In about a week he was well again; and after an interval of several months he is still strong and healthy, though, like most negro children, very susceptible of cold.

It is not usual in this country to meet with tetanus in a child of this age; trismus nascentium generally occurring when only a few weeks old. I lay stress upon this child's not having been exposed to imperfect ventilation, because of the effect found to be due to this cause in the Dublin Lying-in Hospital. Previous to the mastership of Dr. Collins, the disease was rarely absent from that institution: the old practice prevailed of keeping the women hot and smothered up; and the windows being seldom opened, the wards were extremely close and offensive, and a large proportion of the children (I believe one in three or four) died of trismus, or were affected with it. Dr. Collins ordered the windows to be constantly open: the wards became sweet, and trismus from that time became almost unknown. During my six months' residence in that hospital only one case occurred, and that was in a wretched house in the slums of the city.

The cause of the tetanus in this child is not very apparent. It is sometimes produced by worms, but that cause was absent in this instance. I conclude that the tenderness of the spine indicated some inflammatory action in the theca spinalis, which caused the affection to be limited to the extremities. The head was unaffected the whole time, except the spasmodic twitching of the eyelids, which was so different from the permanent rigidity of the extremities that I question whether they had any con-

nexion with each other. This inflammatory origin of the disease derives some countenance from the effects of treatment; for, whilst antispasmodics produced no benefit, the blister, the antimony, calomel, and opium, were followed by marked improvement.

The effect of cold in producing a return of the symptoms was very strongly marked, and great care has been requisite in keeping him warmly clothed since then.

Dr. MACNAUGHT said that it was extremely difficult to account for the occurrence of trismus amongst negro children. He had observed in the West Indies that on some plantations it was for long periods scarcely ever absent, so that hardly a child could be raised upon them, though every care was taken as to ventilation and treatment, at a time when, being slaves, the children were valuable. Without any assignable cause these estates would then become healthy, whilst others which had previously been free from it became affected, and the children died from trismus in them. He had not been able to discover any satisfactory explanation of these facts.

Dr. RAMSAY found in the tropics that the susceptibility of tetanus was about 8 in blacks to 1 in white men.

Dr. NOTTINGHAM remarked that negroes, after losing their fingers from cold, have become tetanic; but he thought that children generally were liable to it after very small injuries: a child pricked its foot with stubble, became tetanic, and died. The woorara poison had been suggested as a remedy in tetanus, and had been used upon horses, which had been kept free by it from the spasm for three quarters of an hour, but died at last. He had dissected a tetanic foot and leg, and found the nerves swollen in several parts between the knee and foot. He inquired whether injury of the *trunk* of the body ever produced fatal tetanus.

Mr. HARRIS mentioned a man who was burnt over the abdomen: the slough separated, and he was seized with tetanus.

Dr. TURNBULL mentioned a man whose scalp was wounded, which was followed by fatal tetanus.

Hernia through the Linea Alba. By Mr. HARRIS.

A YOUNG woman, after her first labour, which was not unusually severe, felt an abdominal tumor, which proved to be a hernia through the linea alba of such extent as to reach from the pubes to the umbilicus, the recti muscles being separated throughout this extent so far as to admit of four fingers in breadth being placed between them, when the hernia was reduced

Interval of several weeks between the Delivery of Twins.

Dr. NEVINS related the case of a woman who was delivered of a premature fetus, and, after a period of six weeks, was confined of a full-grown child, which was still-born.

The case gave rise to a conversation on the subject of superfoetation, in which Dr. LANCASTER said that it was reported to be not uncommon in Australia. When he first arrived there he did not believe in its existence; but so many cases were related to him, by surgeons, of full-grown children being born some weeks after delivery of apparently full-grown fetuses, that he could not doubt nor dispute the evidence.

Dr. MACNAUGHT had made careful inquiry on the plantations in Jamaica, on which cases of superfoetation related by authors were said to have occurred, and he could gain no information of any such events within the recollection of any living person.

Perforation of a Large Artery in the Stomach.

Mr. HARRIS showed the stomach of a young man who had had several attacks of hæmoptysis, varying from a pint to two quarts at a time. An ulcer near the cardiac orifice of the stomach was found after death, which had pierced an artery of sufficient size to admit of a common probe being passed into it.

Scirrhus Mamma.

Mr. BANNER showed a breast in which cancer had proceeded too far, before being placed under his care, to admit of operation. The patient had for many years been subject to pulmonary affections, and the surface of the lungs was found after death to be studded with hard tubercular deposits, which would probably have prevented a favourable result had the breast been removed by operation.

Cancerous Testicle. By Mr. HAKES.

The testicle had been seized hold of some years previously, and had gradually swollen to a large size, accompanied by considerable pain, and still more inconvenience from its weight. The cord was entirely unaffected. On removing it, it was found to contain numerous cavities resembling hydatids, and to be in a state of cerebri-form cancer throughout.

On the Efficacy of the Tampon in Uterine Hæmorrhage.

A paper was read by Mr. JOHN TAYLOR in which he maintained that, in every case of gestation, the tampon acts as a mechanical plug, arresting hæmorrhage:

ture's own way—that of producing a coagulum, without the commonly apprehended danger of converting an open into a concealed hæmorrhage. It has a two-fold action, according to the manner of using it: that is, when the vagina is fully plugged, so as to afford some degree of pressure posteriorly, it invariably produces uterine contraction, terminating in expulsion of the ovum; and, when used more slightly, as a mere pledget, it serves to promote coagulation and stop the bleeding vessels. Different effects can therefore be obtained, according to the intention in view. When efficiently used during parturition, it converts rigidity into softness and expansion, thereby favouring the operation of turning. Contingent on its power of arresting hæmorrhage, it prevents alarming syncope and convulsions, the lacerable condition of the cervix ensuing upon long drainage from the part, and also all the ill consequences resulting from large losses of blood in the early stages of labour, before safe delivery can be accomplished; and he showed that it is equally applicable in the accidental and the unavoidable forms of hæmorrhage before delivery, cases being related from his own practice in proof of these views.

The great danger of forcible delivery under rigidity, and its unprevented sequence—inertia, were pointed out, with the opinions of various authors thereon, both as respects injury to the uterus, and from the often fatal shock of sudden delivery. On these points the tampon was shown to be frequently superior to forcible delivery, on account of the great security it affords from flooding, its slower action in expanding the os, and its being generally more imitative of nature; the apprehension of danger from concealed hæmorrhage being ideal.

The author observed that, although the tampon and artificial delivery are considered as rival powers, enlisting supporters on either side, the former should be regarded as the handmaid rather than the rival of the latter, merely arresting hæmorrhage, producing dilatation by the gentlest means, and enabling the accoucheur to make choice of his future mode of action; either continuing the tampon for the support of uterine action, retaining or loosing the liquor amnii at his pleasure, and relying on the natural powers for the expulsion of the fetus, or turning, as may be thought most expedient, after the necessary amount of expansion has been acquired.

Several fatal cases recorded in the standard have been saved, had the tampon been earlier

NEWCASTLE AND GATESHEAD PATHOLOGICAL SOCIETY.

March 1850.

Case of Closure of the Pulmonary Artery, with Obliterated Ductus Arteriosus and Open Foramen Ovale—Cyanosis.

MR. WALLIS, of South Shields, communicated the following history of this very remarkable and interesting case:—

M. A. Cleet, at 18 years, presented the livid hue of morbus cœruleus, which was permanent and increased by exertion or mental emotion, even the nails assuming a dark livid tinge on such occasions, and the dyspnoea, which distressed her much, then becoming aggravated.

These cyanotic symptoms first appeared twelve years ago, after a fall into a deep pond, in which she was immersed over head, but for how long could not be ascertained: had scarcely been able to go across the room for the last eight weeks preceding her death: the act of rising from the bed brought on an attack of orthopnoea: was able, a few years ago, to walk in the streets, but with great difficulty: employed herself in the house with knitting, sewing, &c.: her disposition, formerly haughty, was latterly more subdued, and she complained of pains in the shoulders, and about the region of the heart, and severe headache, with more than usual oppression about the chest. Nothing abnormal could be heard in the heart's sounds, except that they were sharp and rather distant. Pulse quick, weak, but regular.

On the 28th February, 1850, she was seized with convulsions about 2 o'clock P.M., after which she was comatose, and occasionally convulsed during the evening: moaning on expiration, and died at midnight.

Her mother and friends positively assert that she was perfectly healthy until she fell into the pond when six years old; was ruddy and playful; had neither asthma nor shortness of breath. Since that time she had been afflicted with blueness, palpitation and dyspnoea: menstruated regularly; began three years ago: generally appeared worse after the catamenial loss, and expected the discharge on the day preceding her death.

Post-mortem examination thirty-six hours after death.—Body tolerably well developed for her age; short, and rather stoutly built; mammae and chest of usual size. On removing the sternum the lungs appeared much collapsed, on the left side especially, leaving the heart large and prominent:

lungs crepitant throughout; edges of left lobes indurated and semi-hepatized: the pericardium contained a little more fluid than usual, and the heart appeared large, distended, and considerably loaded with fat; coronary veins dilated and prominent. The heart was removed, and numerous coagula escaped from the distended auricles, which were found connected by a wide opening (the foramen ovale), through which two, or even three fingers, could be passed with ease. The auricles, in fact, formed one large oblong cavity, and a smooth fold of the endocardium, one-sixth of an inch in depth, hanging from the roof of the auricle, was the only indication of the annulus ovalis. The heart was brought away for further examination. Liver large, extending over to left hypochondrium; mesenteric and other veins of abdomen large and turgid;—indeed the whole nervous system was in the same engorged state: spleen a little enlarged; kidneys large and congested; capsules easily peeled off; cortical portion in excess, and enveloping the tubuli to their apices; external aspect of kidneys presented numerous fissures and lobules: each ovary had two projecting vesicles about the size of a large pea, and one or two indistinct cicatrices on its surface.

The heart, on further inspection, presented a very small auriculo-ventricular opening on the right side, scarcely admitting more than one finger, and a few vegetations adhered to the edge of the tricuspid valves: the right ventricle could not contain more than a fluid ounce; its walls were much hypertrophied, half an inch thick; water poured on the tricuspid valves passed slowly, if at all, into the auricle. The most extraordinary circumstance was, that no communication existed between the right ventricle and pulmonary artery, a hard callous contraction precluding all exit in that direction, and a yellowish tendinous state of the endocardium was also observed at the apex of the infundibulum; the pulmonary artery was small, but admitted a finger easily, and ended in a conical *cul de sac*, just above the right ventricle. Air blown into the pulmonary artery found no way of escape. On slitting open the vessel three pouches were seen formed by the adhesion of the semilunar valves to the sides of the artery, and a cartilaginous callosity blocked up the commencement of the artery. A probe did not pass further than a quarter of an inch into these valvular pouches. The left ventricle was dilated to about twice its normal size, its walls being about the thickness of those of an ordinary right ventricle; the proportional thicknesses of the ventricular walls were completely reversed; left auriculo-ventricular opening was healthy, as were the aortic

valves. As the ductus arteriosus had been left in the body, and it was thought that it might have been open, and thus afforded a passage from the aorta to the pulmonary artery, access was again obtained to the body, and the arch of the aorta removed, with what remained of the impervious ductus arteriosus.

Both the heart and the arch of the aorta last obtained were forwarded to Dr. Emberton for more minute examination, and the result of his dissection is now submitted:—

"April 9th, 1850.—The heart sent to me by Mr. Wallis, of South Shields, appears altogether larger than is usual at the patient's age, notwithstanding that it has been some time out of the body, and steeped in spirit and water. Its weight is, however, 8 oz., not more than the average as given by Dr. Clendinning, but rather above the averages of Dr. J. Reid and Dr. Peacock.

The right cavities are totally diminished in capacity, the walls of the ventricle very much thickened, being from $\frac{1}{4}$ to $\frac{1}{2}$ of an inch thick, those of the auricle not so evidently hypertrophied.

The orifice of the pulmonary artery is quite obliterated by adhesion of the free margins of the valves to each other, and to a central coagulum or plug, now quite firm, and undistinguishable in colour and apparent texture from the valves. The calibre of the tube is much diminished at this part, and the valves, though evident enough in outline and having their pouches, are much shrunk in size. The pulmonary artery beyond this occlusion divides, as usual, below and within the arch of the aorta; but the trunk before bifurcation, and the succeeding branches, are all of much smaller dimensions than usual.

The right auriculo-ventricular orifice is very small, corresponding to the state of the ventricular cavity; it is not one-third the size of the left auriculo-ventricular opening. The tricuspid valve is thickened and contracted. The foramen ovale is quite open, and of considerable size. Distinct remains of the valve that normally closes the opening after birth are visible in the form of a narrow, thin, sharp-edged fold of membrane, unbroken, however, and apparently not cicatrized, hanging from the upper and anterior part of the foramen.

The left ventricle appears to encroach upon the right a good deal, and to cause a bulging out as well on the left side of the heart. Its cavity is dilated, and its walls thickened to $\frac{1}{2}$, and even $\frac{3}{4}$ of an inch. The left auricle does not appear materially enlarged; but its walls are thickened. The two auricles form, as it were, only one hamper.

No opening can be discerned between the ventricles.

The aorta appears normal as far as it goes; its arch has the usual primary branches, and it takes the usual course.

The bronchial arteries are normal in all respects, as are also the four uppermost pairs of intercostal arteries; below these the fragment of aorta does not extend.

The ductus arteriosus is quite closed, and contracted at its middle for some distance; it is infundibuliform, and wider below than above. A probe can be passed a short way into it from the aorta, and also from the pulmonary artery; but beyond these parts the ductus is quite impervious. This being the case, and the pulmonary artery being also closed, there seems no route left by which blood could have passed during life from the heart to the lungs for the purposes of respiration, unless the foramen ovale being open, we suppose that it was conveyed in some imperfect way along some of the trunks of the pulmonary veins to the lungs, and returned again by others.

It may be remarked, that both the obliteration of the cavity of the ductus arteriosus and the occlusion of the pulmonary artery had the appearance of long standing."

Disease of Pulmonary Valves reducing the Orifice to the size of a common Quill.

This case occurred in a carman, aged 24, who died in the Newcastle Infirmary, under the care of Dr. White. When admitted he was labouring under general anasarca, with some ascites, had a dusky, puffed out, congested countenance, with blue lips, and complained greatly of orthopnea, palpitation, general oppression of chest and abdomen, and the usual symptoms of confirmed heart disease. The pulse was frequent, weak, and regular. He had been ill for two years, but had only been dropsical for the last three months, and could assign no reason for his illness. The heart was found by percussion to be very greatly enlarged; and a loud murmur was heard at the base of the heart with the first sound, which extended upwards along the sternum: the second as well as the first sound of the heart was very indistinctly heard, the murmurs appearing to come from a considerable distance behind the sternum. His urine was found to be highly albuminous, but of sp. gr. 1.020. Diaphoretics, alteratives, and occasional purgatives, were used for three weeks after his admission, with considerable improvement, until three days before his death.

The autopsy was made twelve hours after death. The pleura and lungs were found to be perfectly healthy; the pericar-

dium enormously distended with six oz. of clear serum, and an immense heart. On opening the pericardium, the right ventricle of the heart were seen of an extraordinary size, occupying the whole of the anterior of the heart, and constituting the apex and principal part of the body of the organ; the left ventricle was with difficulty made out, and existed at the posterior aspect of the heart as a small appendage to the right side. The roots of the great vessels, with the base of the heart, were thrown back to a considerable distance, owing to the great bulk of the body of the organ occupying so large a space immediately behind the sternum. On laying open the pulmonary artery the valves were found to be completely and inseparably glued together, forming a firm and perfect cartilaginous ring, which projected into the tube of the vessel at a right angle to its sides; and, with the exception of a small round aperture in the centre which barely allowed of a common quill to pass through it, completely blocked up the vessel. The artery in front of the valves was very small. The right ventricle was found full of blood, its walls hypertrophied to three or four times the normal thickness, and its cavity capable of holding a very large fist; the auriculo-ventricular opening admitted the whole of the fingers to pass through with ease, and its valves, although healthy, were of course incapable of closing the aperture. The right auricle was dilated to nearly the same size as the ventricle, and was very much hypertrophied: it was distended with blood, and the openings into it of each of the great veins allowed all the fingers, together with the point of the thumb, to enter them, so greatly were they dilated. A firm clot of lymph partially filled the auricle and ventricle, was firmly adherent to the walls of the cavities, and appeared to have been formed some time before death. Both the left auricle and ventricle were much smaller than they ought to have been, appearing as if atrophied, with attenuated, weak, and flaccid walls, and very small cavities; the valves were healthy; the tube of the aorta was only capable of admitting the fore-finger, and had very thin coats. The liver was of great size, nodulated, and presented numerous large hemorrhoidal projections of dilated veins on the surface of the organ; the structure of the viscus was firm, fleshy looking, greatly congested, and the whole hepatic system of veins very greatly dilated and gorged with dark venous blood. Kidneys large, firm, fleshy, and of a dark venous hue, presenting in many parts the cavities of dilated veins.

Mr. Armstrong, of South Shields, related the following case of

Ossification of the Aortic Valves.

Jas. Dodds, *æt.* 49, sailmaker, having applied about twelve months ago with cough, dyspnoea on exertion, &c., was found on examination to be labouring under disease of the aortic valves, accompanied with bronchitis. He was considerably relieved by treatment, but continued ailing, though going about until February 22d, 1850, when he was seized with a smart febrile catarrh, which terminated in pleuro-pneumonia of the right side. His feet and legs became oedematous, he had effusion into both chests, great dyspnoea, and copious expectoration of frothy mucus at first, but afterwards of rusty bloody sputa. In the midst of this attack he was taken with gout in the right and afterwards in the left toe, but it was of short duration. The heart disease and pneumonia formed a serious complication; and, after a protracted struggle, he died on the 16th March. To connect the sounds during life with the appearances after death, Mr. Armstrong read the two following extracts from the history of the case:—"March 4th. Loud rasping murmur with the first sound of the heart, most intense at the arch of the aorta; second sound inaudible; a continuous soft murmur follows the first sound." These sounds were to be accounted for without much difficulty when it was perceived to what an extent ossification of the valves had proceeded. They are described as "forming a rugged chalky ring in the place of the aortic valves, and so contracted as not to admit the finger: this ring is slightly moveable, but could not possibly be closed nor yet much opened during life." "The right auricle and ventricle were much dilated; tricuspid valves healthy; left auricle capacious; left ventricle enormously hypertrophied, walls nearly an inch thick. One of the mitral valves contained a little indurated deposit in its free border."

ACADEMY OF MEDICINE, PARIS.

Local Anæsthetic Medication.

DR. ARAN, member of the Central Board for Hospitals, addressed a note on the value of various anæsthetic agents in reference to local medication. The following are the chief of Dr. Aran's conclusions:—

1. All those volatile agents that are recognized as general anæsthetics possess the same property when applied locally.

2. This local power is not in direct relation to their general anæsthetic power.

but is in an inverse ratio to their volatility. Thus the Dutch liquid, or chloride of olefant gas, exceeds all others; chloroform excels ether, &c. &c.

3. Some of these agents do not produce any irritation of the skin—*e. g.* ethers, aldehyde, and benzine,—while others, as chloroform and Dutch liquid, cause a sense of burning, and, if applied long enough, produce vesication.

4. Therefore the Dutch liquid is the best local anæsthetic agent: its action endures a longer time, it produces only slight stimulation of the surface, and has a less disagreeable odour than the ethers, &c.

5. It is not necessary to employ large quantities for obtaining these local effects: from fifteen to thirty drops of the chloride of olefant gas, covered with a moist compress, will suffice to allay pain in most cases.

Cedema of the Larynx.

M. SESTIER read an essay on this subject, in which he endeavoured to point out its diagnosis and treatment.

Cedema of the interior of the larynx, M. Sestier observed, renders obscure the diagnosis of *angina cedematosa*, by changing one of the principal symptoms of that affection—the facility of expiration as contrasted with the difficulty of inspiration: it further aggravates the danger of cedema of the upper folds of the larynx. In these cases the local applications to the upper part of the larynx are of little use without also active general treatment, such as leeching, croton oil, blisters, &c. Bronchotomy is often to be practised in these cases, as the only means of saving life. According to M. Sestier, however, there is no certain means of the diagnosis of this form of cedema, but it must be gathered from the symptoms generally.

* * There is no form of disease of the air-passages in which the topical application of a solution of nitrate of silver is more beneficial than in cedema about the larynx.

Extraction of a Calculus from the Prostatic Portion of the Urethra.

M. BONNAFORT, surgeon to the hospital at Arras, presented a calculus which weighed twenty-six grammes (=6682 Eng. drachms), was eight centimetres in length (=3.149 Eng. inches), and about two centimetres (=787 Eng. inches) in width at its broadest part. It had the general form of a fish. The patient was thirty-three years of age. He had been operated upon by lithotripsy when six years old, and at the age of thirteen by the

lateral operation; but the calculus being brittle it broke, and the fragments were not all removed. Six months afterwards he experienced great pain at the neck of the bladder, with difficulty in passing water. Suddenly, after strong expulsive efforts, the calculus passed from the bladder into the urethra: some days afterwards it again passed into the bladder. It was subsequently returned into the urethra, where it had remained nine years. Its urethral extremity was round, its vesical extremity thin and pointed.

SURGICAL SOCIETY OF PARIS.

Nov. 20, 1880.

Tumor difficult of diagnosis.

M. MOREL-LAVALLÉE presented a man, thirty years of age, who had been received into La Charité for an inflammation of the arm, of which he had been cured. A tumor, the size of a fist, was observed near the right breast. This growth had existed several years; it was free from pain, and the integuments that covered it were not altered in appearance. On taking it between the fingers it gave a feeling of softness—almost of fluidity; if pressed harder, it was found to consist of granules or lobules, each about the size of a grain of maize. If moved about, it communicated a crepitating sensation similar to that of certain tumors of the wrist described by Dupuytren. A small explorative puncture was made with a lancet, from which there escaped a considerable portion of the tumor, which was thus seen to be a lipoma of an unusual character. The portion that escaped resembled a bunch of grapes, each lobule being attached by a separate stalk to a central stem formed of condensed cellular tissue.

M. LEBERT had examined the structure under the microscope, and found it to consist of fatty and cellular tissue.

M. MOREL-LAVALLÉE had advised the patient not to have the tumor removed.

A Monstrous Fetus.

M. DANTAN presented a monstrosity (of the family *Symeliæ*, genus *Sirénomeles* Geoff. St.-Hilaire). This fœtus was born dead, at the full period, of a healthy mother, and was perfectly well formed in the upper part of its body. The lower part of the trunk terminated in a conical prolongation instead of lower extremities. This prolongation was composed of a thigh, a knee-joint, and a portion of leg about three centimetres (=1.181 Eng. inch) in length, formed of a single pointed bone. The

patella, larger than usual, was not placed on the front but to the left side of the joint. No anal orifice and no external genitals existed. In the place of the latter was a slightly wrinkled fold of integument.

The dissection of this fœtus was not yet complete, but had shown the thigh to be furnished with muscles normal in appearance, but some displaced; the anterior muscles being placed laterally, while others were wanting, or present only in a rudimentary state. The vessels and nerves were placed on the left side. The bone was smaller than usual. In the abdominal cavity the following malformations were observed:—The intestine terminating at the beginning of the rectum by an unattached *cul-de-sac*; the intestinal tube contained meconium; the two kidneys, smaller than natural, were in their usual place, but the ureters and bladder were entirely deficient; the testicles were found in the lower part of the abdomen; the pelvis was a solid mass, with no recognisable form except that of the femoral articulation.

Gun-shot Wound in the region of the Heart.

M. DREUISE exhibited a pathological specimen, of which the following is a brief account:—

An individual was found in the Forest of Vincennes having an extensive wound in the chest: he was taken to the Hospital of Charenton, where he died in about half an hour. On the level of the left breast was an opening of about three centimetres in diameter (≈1·181 Eng. inch), through which the interior of the chest was visible. Portions of the third, fourth, and fifth ribs were removed. The cavity of the pleura contained very little blood. The pericardium presented an opening anteriorly. A bullet was seen to have pierced the wall of the left ventricle, which it had traversed for some distance, but without having entered the cavity of the heart; then passing out, it had again passed through the pericardium posteriorly, and, piercing the lung, was found lodged on the left side of the vertebral column, near the eighth and ninth ribs. The ball was small and round. Near the person of the deceased had been found a brace of small pocket pistols, which had both been recently discharged.

The most remarkable points in this case were the great extent of the injuries inflicted, the absence of hæmorrhage from the lungs, and the duration of life several hours after the receipt of such injuries.

ACADEMY OF SCIENCES, PARIS.

Nov. 18, 1872

Transmission of Sensitive Impressions in the Spinal Marrow.

M. BROWN-SEQUARD read a memoir in which he stated, contrary to the generally received opinion, that the transmission of impressions received by one lateral half of the body is effected in a crossed manner—that is to say, that the right side transmits for the greater part the impressions made upon the left side of the body, and vice versa. According to the opinion which regards the transmission of impressions in a direct line through the cord, the explanation of the phenomena of hemiplegia must be sought in the interlacement of the fibres of the cord in the medulla, pons Varoli, &c. M. Brown-Sequard, therefore, in demonstrating the interlacement of the fibres in the cord itself, has offered a new solution of the phenomena of hemiplegia.

The following are the principal facts on which M. Brown-Sequard founded his opinions:—

After having divided a lateral half of the spinal cord in a mammiferous animal on a level with the tenth dorsal vertebra, it was observed that the limb on the side corresponding to the section of the cord was not only very sensitive, but that it was even more sensitive than in the normal state, while the opposite extremity was very much less sensitive than natural.

The same phenomenon was observed with regard to both limbs on the side of the section of a lateral half of the cord in the cervical region.

If repeated sections of one side of the cord be practised, sensibility remains entire in the limb of that side.

M. Brown-Sequard concludes that the fibres of the cord proceeding from the limbs, and having a connection with the encephalon, must be very few in number.

Employment of Cold Douches in the Lymphatic Temperament.

M. SERRS communicated, in the name of Dr. Louis Fleury, a note on the employment of cold douches in the lymphatic temperament, anæmia, and chlorosis. The following summary presents the chief contents of Dr. Fleury's essay:—

1. That cold douches should be placed in the first rank among restorative remedies by reason of the action which they exert on the capillary circulation, and consequently on the composition of the blood, animal heat, nutrition, and innervation.
2. The lymphatic temperament is modified

fied by those hygienic and therapeutic agents which substitute for it an acquired sanguineous temperament. This agency is attributed by Dr. Fleury to a double action—one on the processes of nutrition and composition of the blood, the other on the capillaries themselves—so influencing their vital properties and contractility, that red globules penetrate where serum alone was admitted previously.

3. The effects of this treatment are manifested first on the digestive organs and muscular system, then on the nervous and circulatory systems.

By these means chlorosis and anemia are also equally effectually cured.

Syphilitic Inoculation.

M. AUZIAS-TURENNE transmitted a note containing his results on this subject. M. Turenne declares the identity of the disease in man and animals. M. Robert de Welz had produced chancres on his arm by inoculation with the matter of chancres previously produced by inoculation in the monkey and the cat. M. Turenne states that, in the successive inoculation of animals with syphilitic poison, each consecutive sore is less inflamed and less characteristic, until at last, after about the fourth inoculation, no effect follows the insertion of the virus. To the state thus induced M. Turenne gives the name of *syphilitization*, from its analogy with vaccination,—as, during its existence, the constitution is protected from syphilitic contagion.

Exaltation of the Sense of Hearing in Paralysis of the Facial Nerve.

M. H. LAXDORFF, Professor of Medicine in the Medical School at Rheims, transmitted an essay containing the following conclusions:—

1. Exaltation of the sense of hearing on the affected side is an almost constant symptom in facial hemiplegia not depending on cerebral disease.
2. This exaltation appears and disappears with the paralysis.
3. It is attributable to paralysis of the muscle of the hammer in the cavity of the tympanum.
4. It indicates that the seat of paralysis is not below the first elbow (*coude*) of the seventh pair.
5. It may exist without facial paralysis.
6. It disappears spontaneously and completely within a period of from fifteen days to three months.
7. To ascertain its existence it is necessary to make an impression on the organ the louder the longer it has existed.
8. Special treatment is useless; cold douches or galvanism have been found useful.
9. This affection lends confirmation to the views of M. Longet on the existence of a motor nerve of the ear analogous to the motor nerve of the eye.

Note on the Contagion and Treatment of Scabies.

M. Bazin addressed a note to the effect that the essay by M. Bourguignon, read at the last meeting of the Academy, contained erroneous statements, and had withheld the fact that to M. Bazin was due the credit of having pointed out the importance of general, as opposed to local friction, in the treatment of scabies.

Hospital and Infirmary Reports.

KING'S COLLEGE HOSPITAL.

Operations for Malignant Growths.

THERE are few operations the surgeon is called upon to perform more frequently than those which are put in force for the extirpation of abnormal growths of the body, which are, or are supposed to be, of a malignant nature; and this is the case, although there has been, and still is, so much difference of opinion regarding the propriety of removing certain malignant tumors. There are those, whose experience and character entitle their opinion to great respect, who strongly advise that malignant tumors should not be meddled with at all, or only under very peculiar circumstances; other surgeons, again, of great repute, do not hesitate to give their patients the benefit of a chance, by employing the knife in a great number of these sad cases. This difference of opinion on such an important point as the extirpation of malignant disease by operative proceeding, depends partly, no doubt, upon the relative amount of success which the individuals in question may have had; and the greater or less success has probably been the result of a more or less happy and judicious selection of the cases for the cure or alleviation of which operations have been performed.

It is not difficult to understand that that surgeon who has had a number of cases of malignant disease to operate upon, which have been of a very bad description, and not well adapted for operative measures, may have formed an opinion that it is better to let such growths alone: a fortunate event has not taken place in any, or but very few cases, and it is but natural that such an opinion should be arrived at. But another surgeon, equally experienced, has, from particular circumstances, the same number of cases under his care,—the disease even may be of the same nature, yet not so inveterate, or of so long standing,—the opera-

tions are here followed by a much greater amount of success: he finds that a fair majority of his patients are relieved of a great deal of suffering, have their lives prolonged, and in some instances are cured, at least for years, by the operative proceedings which have been put in force. Under such circumstances, an opinion more or less favourable to operation is entertained. To a certain extent, at least, the difference of opinion on this point must in this manner be accounted for. It is impossible to ascertain with correctness which opinion prevails most,—that for interference, or that for non-interference with malignant tumors, by the knife. Theoretically, it is probable that the latter does, but practically it must be confessed that the former is in the ascendancy, for a great number of surgeons are in the habit of operating for the removal of malignant growths from the system,—we dare say, too often,—but on the other hand, it is not improbable that many patients suffer a great deal more than they need, and die much earlier, in consequence of neglecting a timely and suitable operation. The best plan, therefore, perhaps in this matter, is to act upon the old maxim, "*in medio tutissimus ibis*;" it is most certainly found to be an advantageous one, in many difficult and important points in medicine and surgery.

Mr. Fergusson is one of those who act cautiously, and steer a middle course relative to this difficult and unpleasant point, of the extirpation of cancerous and other malignant growths. He, on the one hand, does not refuse to operate altogether, nor on the other does he hastily resort to the knife in any case which may present itself. He considers that under favourable circumstances an operation may benefit his patient, and give him a chance of prolonging and saving his life, and he therefore hesitates not, on any suitable occasion, and when there are no serious contraindications, to use the knife.

The practice of this hospital, as of others, has afforded many opportunities of seeing malignant disease, and the results of operations for their relief and cure; and our observation for several years, and of many cases at this hospital, tells us that benefit does accrue to the patients who are operated on for malignant growths; more or less relief is most assuredly given; but it cannot be denied that after a time, when the disease removed has been really malignant, a return in a great number of instances takes place, either rendering second operations necessary, or destroying the patient.

One of the most striking instances calculated to show these truths—viz., that malignant disease may be eradicated for a time by the surgeon's knife, and that life

may be considerably prolonged, and that a recurrence of the disease is too apt, even in apparently favourable cases, to take place sooner or later, was in the hospital during the last year under the care of Mr. Partridge. The patient was admitted with a large fungoid tumor, which was situated in the thigh, just in front of the femoral vessels, as they run along Scarpa's triangle, and encroaching somewhat on Poupert's ligament. The size of the tumor was very considerable, being nearly as large as a man's head.

Now this patient, who was a man hardly in the prime of life, applied at King's College Hospital three years prior to this, he having at this time a large fungoid tumor, situated in the posterior part of the leg, of the same side. Mr. Partridge extirpated the mass; the man recovered from the operation, returned to his occupation, and continued in health for a long period: a return, however, of the same disease takes place ultimately. The cicatrix of the old wound in the leg was perfectly healthy, and the disease was now entirely confined to the upper portion of the thigh. Mr. Partridge again operated; unfortunately erysipelas took place, and the patient died from this cause.

This case itself is an argument in favour of removal of malignant growths, when they can be entirely taken away, although the same kind of disease returned at a subsequent period: had not the original malignant tumor been taken away, it is probable that the patient would not have lived half so long as he did, and, moreover, he would have been in a state of constant pain and misery; but the operation kept him free from suffering for a few years at least, and had not an accidental attack of erysipelas carried him off after the second proceeding, he might have lived for as many years more.

It is to be borne in mind, that there was a greater likelihood of temporary success here, from the situation of the original growth, although it was a fungoid tumor: when a fungoid growth is seated in the orbit, in the substance of the testicle, or within the cavities of the nose, there is a much less chance of success after an operation, because it too often happens that similar deposits are co-existent within the internal organs, or they soon involve them; but when the growth is on one of the extremities, and a considerable distance from the trunk, there is less danger of simultaneous disease in internal organs; consequently the chance is more favourable for recovery after operation.

A case where the arm was amputated for malignant disease was in hospital at the commencement of the present year under the care of Mr. Fergusson: it well illus-

trates the peculiarity of malignant disease to return after a time, as well as the relief which is given by operation. The patient was a healthy-looking labouring man from Kent; and several months previous to the amputation being resorted to, he applied, in consequence of an ulcer situated on the back of the wrist; it was as large as a crown-piece, and it presented that peculiar appearance which denotes malignant action: it caused severe pain; and moreover it was entirely intractable to the remedial measures which were employed. Mr. Fergusson therefore removed the entire ulcerated surface with the knife, carrying the instrument well beyond the edges of the sore, so that none of the disease should be left behind. After the operation the wound rapidly cicatrized, and it was almost entirely healed up, and presented a healthy cicatrix, when the patient left the hospital. In the course, however, of a few months he returned again with a sore on the same spot, and of the same appearance. It produced considerable pain, and shortly before his application a considerable hæmorrhage had taken place, which had caused the man some fear. It was very evident that it would be useless to attempt to remove the disease entirely without removing the arm as well. Mr. Fergusson therefore amputated in the forearm sufficiently high up for the flaps to be away from the disease. A speedy cicatrization of the stump took place, and the patient left the hospital in a few weeks very much improved in his health. This man lately presented himself, when it was seen that the stump of the amputated arm continued in a perfectly healthy condition, and there was not the least appearance of implication of the cicatrix in the original disease. The patient presented all the appearance of vigorous health. Just over the inner condyle of the humerus, however, is a swelling of some size, painful on pressure, and soft. This he has noticed now for some months, at first being very small and hard. It is impossible to state at present whether this is merely an enlarged and inflamed gland proceeding to suppuration, or whether it is a return of malignant disease in that situation. The hopes of the surgeon suggest the possibility of the former, but his fears lead him, not without reason, to expect that it may probably be the latter. The patient has been desired to return again shortly; and we shall make a point of watching and recording the issue of this case.

The observations which have been made with reference to the nature and treatment of cases of malignant growth apply in particular to scirrhus tumors of the mammae. There have been, and are now, in the hos-

pital several cases of interest, and illustrative of what has been remarked with respect to the propriety of removing certain cancerous growths with the prospect of giving relief for a time; also as regards the probability of a return of the disease sooner or later after operation.

There is one case in particular now under treatment which shows the validity of these assertions. A patient, of the name of Peel, a married woman, aged 32, without family, was admitted into the house in October for the purpose of having a morbid growth removed from her right axilla. Her history is as follows:—

About three years ago she first noticed a swelling in her right mamma, which gradually increased in size, and at the end of a year produced so much uneasiness, that she applied to Mr. Fergusson, who pronounced the swelling to be a cancerous tumor of the mamma, and advised operation at once, as there was no implication of the axillary glands, and the health was in other respects good. The operation was performed in February 1849. The tumor was found to be scirrhus. The wound healed up kindly, and the patient was discharged the hospital, and her health soon became perfectly restored. About three months afterwards, however, she felt a small lump in the axilla of the same side. This gradually and slowly increased in size, and latterly gave her pain. Her health nevertheless continued excellent. At the expiration, however, of two years, she became more anxious about the swelling, as it had increased in size, for it had become as large as an egg. Mr. Fergusson therefore advised her to come into the hospital and have the tumor removed, as he had little doubt of its being a scirrhus gland. The cicatrix of the wound made in the old operation was perfectly sound, and there is not the least appearance of return of the disease in that spot. The operation of removing the gland from the axilla was performed on November 16th. The morbid growth was situated so close to the large vessels and nerves in this important space, that Mr. Fergusson was obliged to dissect with very great caution: in fact, the tumor lay just over the axillary artery; and when it was removed the pulsations of the latter could be easily seen in the wound, and the vessel might readily have been wounded without due caution having been exercised. On cutting into the mass it was found to be a gland degenerated into scirrhus. One or two detached and smaller glands were taken away, so that none of the disease should be left behind. This case also will be a very interesting one to watch. This poor woman has certainly received great benefit from the original

operation, and it is to be hoped that she may be spared for some time, or altogether, from the further effects of the disease.

The success after the excision of a scirrhous breast will depend, in a great measure, upon the period at which the operation has been performed—much, also, upon the condition in which the parts are at the time. This of course holds good not only with reference to cancer of the breast, but in like manner to the similar affections in other portions of the body. It would be useless to extirpate, with any hopes of success, a cancerous tumor of the lip, if the sub-maxillary glands are at the same time affected with the disease, or if the growth itself has extensively involved the mucous membrane of the mouth and gums. In like manner, no ultimate benefit can be expected if an operation should have been performed for a cancer of the penis, if at the same time the glands of the inguinal region are contaminated by the disease. It is of equal importance to select the cases of scirrhous mammae. There will be little hope of doing good if the tumor has existed for a long time, and has become adherent to the skin above, and if at the same time the glands of the axilla are affected by the disease; but if the growth is not of long standing, is perfectly circumscribed, and the skin over it is not adherent or diseased, and if there is no implication of the axillary glands, and no symptom of constitutional disease, the surgeon may operate with the reasonable hope of benefiting his patient; and, if she be willing and anxious to have it done, the surgeon is only doing his duty in according to her wishes in such a case. The following is an instance where everything was so favourable for an operation, inasmuch as the disease was entirely confined to the breast, was not of very long standing, and there was nothing to contraindicate the proceeding.

Sarah Pratt, aged 45, unmarried, menstruates regularly, was admitted into King's College Hospital, Nov. 6th, under the care of Mr. Fergusson, with a tumor of the right mamma. She states that 15 months ago she first felt an aching pain in that situation, and subsequently a lump made its appearance on the outer side of the mamma, below the nipple. When first perceived it was the size of a walnut: it increased in size, and the pain in it became constant, and this was aggravated when anything pressed upon it. It continued, however, stationary, for some six months, but during the last nine months it has increased in size with rapidity; the pain has become worse, and changed its character from aching to lancinating. On her admission the tumor was found to be about the size of an orange; it was excessively

hard to the touch, and perfectly circumscribed, very moveable, and unadherent to the skin, except just at the lower part, where the latter is slightly discoloured; the nipple not retracted; no enlargement of the axillary glands; health very fair. Here was an instance where an operation might be performed: there could be no doubt of its being a scirrhous tumor. Mr. Fergusson therefore removed it in the ordinary manner; and, on cutting into it, the whole of the gland was not affected; the upper part was healthy, but the lower portion was decidedly cancerous. This patient is doing well; and it is to be hoped that some immunity from the terrible disease will be granted her through the instrumentality of this operation.

Although in this case the entire mammary gland was not involved in the disease, it was deemed advisable that the whole of it should be taken away; and there can be little doubt that in the majority of instances where a portion only is affected—of course it being plain that the disease is cancer—the entire gland should be extirpated. If only the apparently affected part be cut away there is a very great danger of its speedy return; for during an operation, when there is a good deal of bleeding going on, and the normal appearance of parts is altered, it is not an easy thing at all times to distinguish with accuracy the healthy from the diseased tissues: a part of the mammary gland may still be contaminated by the scirrhous deposit, and be left behind in this condition. In such a case there will certainly be a speedy return. It is therefore more safe, and more humane towards the patient, to extirpate the entire gland. Cases, of course, will sometimes present themselves where there is only a very small and circumscribed induration, and where it is very possible to remove the disease effectually without amputating the whole breast, but these are not frequently seen, especially amongst hospital patients, as they too often do not apply for advice until the tumor has involved, more or less, the whole of the organ. When, therefore, there are doubts as to the extent of the scirrhous deposit, it will be far better to cut out the whole mamma. Cases are every now and then recorded where operations have been performed for cancer of the breast, and where only a portion of it has been removed. The disease has returned, and the patient has been compelled to submit to a second operation, at which the whole has been removed, and with very good and in some cases lasting success.

However unpleasant the task, and however melancholy it is to reflect that in a large number of cases a return of cancer is to be expected after an operation has been

put in force, it is nevertheless incumbent upon the surgeon to give the patient the chance of an operation, if she is anxious to have it performed, and if the circumstances of the case are in any way favourable for a good result. Operations of this nature are not generally very willingly undertaken by the surgeon, nor are they in any great way creditable to surgery; but it is the duty of the former to give relief even if he cannot cure: and it should be borne in mind that now-a-days, under the use of chloroform, these operations are divested of the greatest amount of horror and aversion by which they were contemplated by the patient. This is an additional argument in favour of operating for cancer of the breast. It was perhaps a question in former days, in a great number of cases at least, as to whether the relief which was given through the use of the knife was a sufficient compensation for the terrible suffering endured from it; but this state of things fortunately no longer obtains, and the surgeon has the consolation of feeling that, although he is performing a disagreeable task in operating for cancer, the proceeding itself is now robbed of the character which but lately formed the main, or one of the main objections to it.

HÔPITAL DE LA CHARITÉ, PARIS.

A Case of Pneumo-Thorax, with Remarks on the Disease. Under the care of M. RAYER.

THE labours of modern pathologists have left few points respecting this serious disease in obscurity. It would seem, indeed, that from the researches of M. Saussier, in 1841, the more recent investigations of Dr. H. M. Hughes (LONDON MEDICAL GAZETTE, 1844), and the thesis of M. Marais, in 1846, that there remains but little to be pointed out of interest or importance regarding it. Nevertheless, as this disease, without being rare, is happily far from frequently met with in practice, it is as well from time to time to publish its more striking instances, in order to familiarize the professional mind with its characters, and to elucidate such questions connected with it as may yet possess some obscurity.

According to the investigations of M. Saussier, the occurrence of pneumo-thorax with phthisis takes place twice as frequently on the left as on the right side. Of eighty-one cases collected by him, this disease was found to exist fifty times on the left side, and once on both sides, which he attributes to the greater frequency and more rapid progress of phthisis in the first

than in the second cases. He admits that perforation may take place where phthisis is but little advanced, if the tubercle be near the surface of the lung. Dr. Hughes, to whom science is indebted for a very remarkable contribution on this subject, states an opposite conclusion—viz. that pneumo-thorax is more frequently met with on the right than on the left side, and, moreover, that it co-exists now and then with a single small pulmonary cavity. M. Chomel goes even farther than the English pathologist, and asserts that it may occur where tubercular disease in the lungs is but very slightly advanced, or is inconsiderable in its extent. It has occasionally happened, M. Rayer added, that opportunity has occurred of confirming the justice of the remarks of the celebrated professor of the Hôtel Dieu.

In the case now under consideration the morbid changes were even less advanced on the side where the pneumo-thorax had occurred; affording a striking illustration of where the truth lies—whether with M. Chaussier, or with MM. Hughes and Chomel; nevertheless further documents are wanting to decide the point.

This disease has usually been considered of so grave a character as to be always fatal. This has been somewhat exaggerated. A young man under M. Gendrin's care was quickly cured by paracentesis, although presenting evidence of phthisis. Its curability is obviously dependent on the closure of the fistulous opening from the lung; if this can be obtained, and if it coincides with only a few tubercles, or a small cavity, there is no reason why the cure should not take place, as we know sometimes happens with tubercular cavities. Let us see, then, if pulmonary fistulae of a tubercular nature be susceptible of obliteration. On this point M. Saussier observes, that these fistulae are only apparently closed, in consequence of the development of a second false membrane more or less thickly deposited over their orifice, and by which communication between the pleura and the cavity is cut off. This question also requires further investigation: in the meantime M. Chassier's solution may be admitted with reservation. Doubts on this point are warranted by three cases related by M. Marais, two of which are published as cases of pneumo-thorax without perforation. Although the autopsy may have been conducted by the most competent persons, it is impossible to admit that pneumo-thorax can be produced in patients whose lungs are healthy, and cavities, at places had simply existed in the

third case, where the adhesion of the membrane was so firm that inflation of the lungs made no impression upon it. In other cases the healing of the fistulae must be admitted.

In the following case death took place so rapidly that treatment was useless:—

A man, aged forty-two years, was received in the hospital of La Charité (Saint Michael's ward, No. 33), who had for several years presented signs of phthisis. While under M. Rayer's care the existence of a cavity was ascertained at the upper part of the right lung; under the left clavicle only dulness on percussion and deficient respiratory murmur were discovered. In the night of the 5th of November he suddenly experienced severe pain at the lower part of the left side of the chest. The expectoration, which had before been abundant, ceased from this time. A tympanic sound was audible in the lower part of the chest on the left side, with enlargement of the thorax at that part. The respiratory murmur was replaced by an amphoric sound, accompanied frequently with slight metallic tinkling. It was not possible by succussion to produce thoracic fluctuation. Death took place on the evening of the same day.

On examination of the body, the right lung was found riddled with tubercles, hard and soft, with close adhesion of the surfaces of the pleura. On puncturing the left side of the thorax an escape of gas took place, producing its characteristic whizzing sound: the left lung was pressed back against the vertebral column, and was only slightly adherent at its upper part. By inflating the lungs, a perforation of about two millimetres (= .7874 Eng. inch) was found at the upper part of the lower lobe, which communicated with a small cavity; this, at its outer side, had been only separated from the cavity of the pleura by the serous membrane.

A child was brought to the hospital in August 1849: it was then three weeks old: the mother had perceived some hardness about the neck for several days, of which she took little notice until the skin began to look red. Upon examination, the sterno-cleido-mastoidous on the right side, especially in its lower half, was hard and well defined: the child evinced considerable uneasiness upon manipulation: the surface was red, and the heat of the skin increased, with marked constitutional symptoms. An evaporating lotion, with poultices at night, and alterative doses of Hyd. c. Creta, were prescribed. The application of leeches was suggested, but deferred on account of the age of the child. In two or three weeks it was so much better that a liniment was ordered, and the case marked off the book. Upon subsequent examination it was found that no induration or perceptible change remained. The child, a male, presented with its breech, was above the average size, and more than usual difficulty was experienced in its extraction. The woman's two previous labours had been of a similar character: the children were both born dead: she was attended by an experienced practitioner, who considered the brim of the pelvis small.

The affection at the time was considered to have arisen from injury received in the birth.

I should scarcely have considered it worth narration but for the mystery thrown over it by Mr. Curling's note. I make no doubt similar cases arise from violence applied in one way or other. The exact condition of the muscle is not so easily ascertained, as it is not very likely to fall under the scrutiny of the pathologist. If this is sufficient to remind some of my fellow junior practitioners of the sage aphorism about meddling midwifery, my purpose will be abundantly served.

J. BASSETT,

Late Resident Medical Officer to the Birmingham Lying-in Hospital.

Great Hampton Street, Birmingham.

Correspondence.

ON INDURATION OF THE STERNO-CLEIDO MASTOID—LETTER FROM MR. BASSETT.

SIR,—The communication of Mr. Curling in your last number, respecting induration of the sterno-cleido-mastoidous muscle, caused me to refer to my note-book, in which I find an account of a case which occurred during my residence at the Lying-in Hospital in this town, of, I apprehend, a similar nature, except that it was in an inflammatory condition, the cause appearing quite obvious.

ON INDURATION OF THE STERNO-CLEIDO MASTOID IN INFANTS.

SIR,—In your last number there is a short paper from Mr. Curling on Induration of the Sterno-cleido-mastoidous muscle in Young Infants, in which he states that the left muscle was affected in all the cases he saw, and throws out a suspicion that it arose from some injury during its birth. The following case will, I think, render it very probable that Mr. Curling's suspicion as to the cause is correct: at the time of its occurrence I had no doubt that laceration of some of the fibres of the muscle

was the cause, and mentioned it to the parents; but in this case the right sterno-cleido-mastoideus muscle was the seat of the affection.

A lady in labour with her first child, which presented with the breech, progressed slowly but favourably till the expulsion of the breech, when, after waiting some time, and no progress being made, I brought down a fold of the funis, and found the funic arteries beating very quick and intermitting. For the safety of the child, it was necessary to expedite the labour. I drew down the body as far as I could, disengaged the arms, and then proceeded to deliver the head: it was situated high up, and required its direction to be changed: in doing this, difficulty was experienced, but the child was speedily born alive. Upon examining the child a short time after its birth I discovered a small swelling in the situation of the middle third of the right sterno-cleido-mastoideus muscle: on slight pressure the child showed signs of uneasiness. The impression on my mind at the time was, that in the forced expulsion of the head a few fibres of the muscle were lacerated, and perhaps a little blood effused at the same time. The next day the swelling continued, and the muscle was found hard, defined, and painful, and the child naturally kept the head to the right side. Fomentations were applied. This state continued for many weeks, when the induration gradually subsided; but the swelling continued for eighteen months after birth, and then by degrees disappeared. I saw the child a day or two ago, now upwards of three years of age, and there is no difference between the two muscles.

Yours respectfully,

SAMUEL BERRY,

Professor of Midwifery, &c., at Queen's College, Birmingham, and Surgeon-Accoucheur to the Queen's Hospital.

Birmingham, Nov. 27, 1850.

Medical Intelligence.

UNIVERSITY OF LONDON.

M.D. EXAMINATION—1850.

Examination for Honours.

Monday, November 25.—Morning, 10 to 1.

Elements of Intellectual Philosophy, Logic, and Moral Philosophy.

Examiner, Mr. BURMAN.

1. "There are and can be but two ways of investigating and discovering truth."

What are these two methods, and what is the difference between them as regards the process of the mind?

2. One of the operations which the word Induction has been used to designate, is "the *material* illation of a universal from a singular, as warranted either by the general analogy of nature or the special presumptions afforded by the object-matter of any real science." Show that this is the process of Bacon, and distinguish between it and the Aristotelian Induction.

3. Enumerate the causes or sources of the *Idola Tribus* and the *Idola Theatri*.

4. Give Stewart's definition of consciousness. How, according to him, do we get the notion and conviction of our personal identity? Give any other solution of the question.

5. "It is to the use of artificial signs that we are indebted for all our general conclusions, and without it our knowledge would have been entirely limited to individuals." Give reasons for or against the above proposition.

6. "To what part of our constitution is the origin of our ideas of right and wrong to be ascribed?" How is this question answered by Hobbes, Cudworth, Locke, and Hutcheson? How do you answer it yourself?

Cousin and Butler.

Examiner, Rev. H. ALFORD.

1. What, according to Locke, are the sources of all our ideas? How does he on his theory account for the ideas of space, time, infinity, personal identity, substance, causality?

2. What fundamental error pervades the whole of this part of Locke's system? How has it been carried out since his time, and by whom? What are, according to Cousin, its principal merits and demerits?

3. Give Cousin's refutation of Locke's view, that all judgment is founded on comparison.

4. What are the presumptions that we shall live after death, deduced from our present physical, intellectual, and moral state?

5. How is God's government by punishments justified by analogy? "In the natural course of things, virtue *as such* is rewarded, and vice *as such* punished." With what exception is this true? What may be inferred from the rule, and what from the exception?

6. Show that the government of God must be a scheme incomprehensible to us at present.

[To be continued.]

ANNIVERSARY MEETING OF THE ROYAL SOCIETY—ELECTION OF OFFICERS.

THE anniversary meeting of this Society was held on Saturday last, the 80th ult., being St. Andrew's day. There was a good attendance of Fellows, among whom we observed the Marquis of Northampton, Chief Baron Pollock, Sir R. Inglis, and Professor Faraday.

The President, the Earl of Rosse, read the annual address, which gave a retrospective view of the progress of scientific discovery during the past year, chiefly in the sciences of physical astronomy and mathematics. It adverted to the deaths of two eminent foreign Fellows—namely, MM. Gay-Lussac and Blairville. After the reading of this address, the Copley medal was awarded to Professor Haunsteen, of Denmark, for his researches in astronomy; the Rumford medal, to M. Arago, for his numerous discoveries and improvements in optical science. The Royal medals were awarded to Professor Graham, of University College, for his contribution to the Transactions of a paper on the Motion of Gases through Tubes; and to Mr. Brodie, son of Sir Benjamin Brodie, for his paper on the Chemical Constitution of Wax.

An obituary memoir of Gay-Lussac was read in its original French by Mr. Christie, one of the secretaries.

Lord Northampton moved a vote of thanks to the noble President for his valuable address, and a resolution to the effect that it should be printed for the instruction of the members. This was seconded by Sir R. H. Inglis, and carried unanimously.

The balloting for officers for the ensuing year was commenced, and the following noblemen and gentlemen (constituting what is termed the House list) were elected:—

President.—The Earl of Rosse, K.P., M.A. *Treasurer*.—Lieut.-Col. E. Sabine, R.A.—*Secretaries*.—Samuel Hunter Christie, Esq., M.A.; Thomas Bell, Esq., Foreign Secretary.—*Captain W. H. Smyth, R.N.* *Other Members of the Council*.—John Joseph Bennett, Esq.; William Bowman, Esq.; Sir Benjamin Collins Brodie, Bart.; The Rev. Professor Chalkis, M.A.; Lt.-Gen. Sir H. Douglas, Bart., G.C.B.; Sir P. de Malpas Grey Egerton, Bart.; John Forbes, M.D.; Marshall Hall, M.D.; Gideon A. Mantell, Esq., LL.D.; Professor W. Hallowes Miller, M.A.; Sir R. Impey Marchison, M.A.; Richard Phillips, Esq.; Rt. Hon. Sir Frederick Pollock, M.A.; George Rennie, Esq.; Edward Solly, Esq.; Lord Wrottesley.

The Fellows whose names are in italics were not members of the last council.

The funds of the Society appear to be in a flourishing condition. During the last seventeen years there has been a steady increase in the annual contributions from Fellows. We subjoin an account of the contributions during the last ten years:—

1841	815	12	0
1842	910	8	0
1843	933	16	0
1844	1025	16	0
1845	1010	0	0
1846	1074	0	0
1847	1116	8	0
1848	1122	16	0
1849	1130	16	0
1850	1146	4	0

The total receipts during the past year, exclusive of the Balance, amounted to £3176. 19s. 6d.

The Expenditure during the same period, exclusive of the sum of £600 invested in the Funds, was £3000. 5s. 7d.

Under the head of *Donation Fund*, the Society has paid £250 during the past year to the under-mentioned gentlemen:—

Donation Fund.—Dr. Hofmann, for Chemical Investigations, £100; Mr. Miller, for Meteorological Observations, £50; Mr. Newport, for Physiological Investigations, £50; Dr. Frankland, for Chemical Investigations, £50.

The oppressive character of the Income tax is shown in this as in other scientific societies. Upwards of forty pounds per annum are paid for this impost out of the funds devoted to *scientific* purposes! In a revision of this most unjust and oppressive, tax we consider that the property of all societies whose funds are devoted to the purposes of science, should be exempted.

BOTANICAL SOCIETY OF LONDON.

THE fourteenth anniversary meeting was held on Friday evening last at the Society's rooms, 20, Bedford Street, Strand, Mr. J. E. Gray, F.R.S., president, in the chair. Mr. G. E. Dennes, the secretary, read the report of the Council, from which it appeared that fifteen new members had been elected since last year, and that the Society consisted of 250 members. Many thousands of specimens of British and foreign plants had been distributed to the members, and increased exertions had been made this year to extend this important department of the Society's operations. The report was unanimously adopted, after which a ballot took place for the Council, when the president was re-elected, and he nominated Mr. J. Miers, F.R.S., and Mr. A. Henfrey, F.L.S., vice-presidents. Mr. J. Reynold and Mr. G. E. Dennes were elected treasurer and secretary. The members afterwards supped together at

he Sussex Hotel, Bouverie Street, Fleet Street.

LAW OF LUNACY.

WE understand that, at the instance of an influential member of the American Government, Dr. Forbes Winslow is actively engaged in preparing an analysis of the English Law of Lunacy. Dr. Winslow is requested to make any suggestions that may occur to him in the course of the inquiry, relative to an amendment of the law. We trust, when Dr. Winslow's labours are brought to a conclusion, that the results of the investigation will be submitted to the British Government, in order that they may adopt any valuable suggestion it may contain for an amendment of our own defective laws, in regard to the arrest and detention of persons alleged to be insane.—*Morning Chronicle*.

CHARING CROSS HOSPITAL.

DR. ROWLAND has been recently elected Assistant-physician to this Hospital.

MEDICAL STUDENTS IN PARIS AND LONDON.

L'Union Médicale reports that there has been a great increase this year in the number of students attending the medical schools of Paris. In 1849 there were 880 inscriptions only: in 1850 the number has risen to 1223. The registrations in London for the present session are said to amount to 1035—a number which is larger than the average.

APOTHECARIES' HALL.

NAMES of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, 28th November, 1850:—William Frederick Bassett; Mark Rowland Day, Oxford; George Frederick Gwyn, Long Stratton, Norfolk; Charles William Hammond, Ipswich.

OBITUARY.

At St. Omer, on the 24th ult., Maitland Maitland, M.D., in the 91st year of his age.

Selections from Journals.

CASE OF DISEASE OF THE LYMPHATICS. BY DR. FETZER, STUTTGARD.

ALTHOUGH cases are on record in which, as the consequence of wounds, the fluid of the lymphatics has been seen to flow directly from those vessels, observations are wanting of the spontaneous affection of one or more lymphatic vessels attended

with escape of their lymph. The following case is therefore interesting, and the more so as it is authenticated by Prof. Schlossberger's analysis of the fluid:—

A girl, 16 years of age, had not menstruated; she was otherwise in good health, but had been the subject of double crural hernia since the age of eight years. In the course of the year 1847 she noticed several small mamillary prominences on her abdomen. She, however, took no notice of them, until, towards the end of Jan. 1847, she was persuaded to consult Dr. Fetzer. On examining the abdomen, there was discovered a long brownish-coloured stripe, about three fingers in breadth, extending to an inch below the umbilicus to the left of the middle line, and upwards and backwards towards the dorsal vertebra, but gradually decreasing in size and colour. About an inch below the umbilicus, and two lines to the left of the linea alba, was situated a mass of tumors, eighteen in number, of the size and shape of the female nipple; their colour was the same as that of the surrounding integuments, insensible to the touch, and it could easily be made to disappear by pressure; but they quickly reappeared on removal of the pressure. The patient had for a long time experienced slight lancinating pains in the course of the strip of discoloration, but had not paid any attention to them.

In July, whilst out walking, and being in great haste to return home, a quantity of fluid escaped from the surface of the abdomen. This fluid, at first milky, became grumous. Three days afterwards this flow returned, and continued three days. A milky fluid was seen to ooze drop by drop from the centres of two of the largest tumors. According to the mother's testimony, the girl had lost at least a litre (= 1.76 Eng. pint) of fluid. By compression of the tumors the quantity could be increased. By the aid of a lancet a minute red point moistened with fluid could be detected on each nipple. The fluid, when collected, separated, at longer or shorter intervals, into a turbid milky serum, and a clear, tolerably abundant coagulum, which became reddened by exposure to the air.

Dr. Fetzer removed one of these tumors with a pair of scissors: it was formed of the layers of skin somewhat thinned. The duct being open, a probe could be passed in to the distance of an inch, either right or left. A quantity of fluid flowed from the orifice, which neither pressure nor strong solution of alum arrested, and which yielded only to the repeated application of nitrate of silver. It was of importance to arrest the flow, as the patient felt weakened thereby, and the pulse was becoming smaller. After the eschar formed by the nitrate of silver

had been cast off, the former tumor remained, and a number of smaller growths, varying from the size of a millet seed to that of a lentil, also appeared.

The fluid which exuded presented all the characters of lymph. It was constantly of a turbid milky aspect, whether collected after a meal or fasting. The turbidity was owing to the presence of fatty particles: ether rendered it clear.

The tumors were probably dilatations of the lymphatic vessels consequent on obstruction of a trunk—the effect of slight inflammation indicated by the previous lancinating pains. Examined microscopically, a great number of fat-granules were observed in the liquid, having an active molecular movement. Lymph-globules, nearly spherical, slightly yellowish, and containing nuclei of various sizes, were also seen; also unnnucleated corpuscles, fewer in number, less regular, of a yellow colour, smooth surface, seeming to constitute a transition state to blood-globules, and to which might be owing the reddening of the liquid on exposure to the air.

Prof. Schlossberger's analysis gave for the composition of 1000 parts of the blood—

Water	930.68
Albuminous substances	47.26

13. Sudden Deaths.	3
14. Violence, Privation, Cold, &c.	24

The following is a selection of the numbers of Deaths from the most important special causes:

Small-pox	14	Convulsions.	35
Measles	25	Bronchitis	64
Scarlatina	32	Pneumonia	67
Hooching-cough	33	Phthisis	96
Diarrhoea	13	Lungs	3
Cholera	0	Teething	11
Typhus	47	Stomach	3
Dropsy	12	Liver	13
Hydrocephalus	19		
Apoplexy	21	Childbirth	7
Paralysis	22	Uterus	3

REMARKS.—The total number of deaths was 305 below the average mortality of the 48th week of ten previous years.

NOTICES TO CORRESPONDENTS.

We shall have great pleasure in giving insertion to Dr. F. J. Brown's case of Softening of the Cerebellum. It shall appear, if possible, next week.

Mr. R. Oke Clark's communication shall have early insertion.—Owing to the comparatively small number of Subscribers, the plan of publishing a General index has been for the present abandoned.

Dr. J. Pollock's second paper has been received. The first part of Dr. W. S. Kirkes' contribution will be inserted in the following number.

We regret that we are obliged to postpone Mr. Gallwey's paper, and the Guy's Hospital Report, until next week.

The notice of the Reports on Cholera in the Yorkshire Asylum is written, and will shortly be published in an article with reviews of sixteen other works on Cholera. This will explain the delay in noticing this and several other essays on the disease.

Mr. T. W. Nunn.—The report was received too late for this week's number. A private letter will be sent.

RECEIVED.—Mr. Huxley.—Dr. Wright.

Lectures.

CLINICAL LECTURE

ON

ASTHMA.

(Delivered at King's College Hospital, Oct. 18, 1849.)

By R. B. Todd, M.D. F.R.S.

Physician to the Hospital.

[Reported by H. H. Saltzer, M.B., Dem. Anat. K.C.L.]

LECTURE XV.

I SHALL call your attention to-day, gentlemen, to the subject of Asthma; and I shall take, as the text of my remarks, the case of John Shaw, who, you may remember, was admitted into the hospital on the 4th of this month (Oct. 1849), labouring under a very violent asthmatic paroxysm, but who is now, I am happy to say, quite well.

As the case is given very concisely, and yet accurately, I may as well read it to you:—"The patient, by occupation a cab-driver, states himself always to have been a tolerably healthy man, with the exception of two attacks of fever, the last of which was very severe, and for which he was treated some months ago in this hospital. Soon after leaving the hospital he returned to his ordinary occupation, which necessarily exposed him to every vicissitude of weather, and this he makes an excuse for having drunk very freely of rum, and other spirits.

"For the last two or three months he has been gradually becoming asthmatic, having at all times more or less difficulty of breathing, the dyspnoea, however, being aggravated greatly by any exposure to wet or cold, and the paroxysms of dyspnoea always ending in violent cough and expectoration.

"On October 3d he drank pretty freely of spirits, and was greatly exposed on a very wet day—one of those wet days which prove a harvest to the London cabmen: he went to bed early, but found himself unable to lie down, and therefore passed the night sitting up; and, in spite of this position, much troubled with difficulty of breathing. At last he fell asleep, but was awake early the next morning by a fresh paroxysm of asthma. The dyspnoea greatly increasing, he was brought to the hospital at five o'clock in the morning.

"Upon examining his chest it was found

to be large and barrel-shaped, very resonant on percussion at all points, even over the cardiac region; the heart could be felt and heard beating at the scrobiculus, and only in this region or a little to the left of it, but not in the normal situation; very distinct rhonchus could be detected over the whole of the chest, and at some points sibilus could be distinguished. The heart could only be heard in the epigastrium: he expectorated a good deal of thick, viscid mucus, but not without much difficulty and cough." So far for the report.

At two o'clock, when I came to the hospital, I found him sitting up, suffering from extreme dyspnoea, blue in the face, with all the ordinary and the accessory muscles of respiration working actively; and I then determined to try the effect of chloroform, and applied it at once, not pushing the administration of it so far as to procure complete insensibility. After a few whiffs he experienced an evident relaxation of the asthmatic spasm; he breathed slower and easier; his pulse became slower and fuller; and, from that moment, the paroxysm seemed to give way.

After the influence of the chloroform passed off, the dyspnoea returned, although in a much less degree, but only for a very short time: he passed the remainder of the afternoon without suffering, and slept well.

The next morning (Oct. 6th) the following report is made:—"He is decidedly better, has expectorated pretty freely, breathes much more easily, and his pulse has fallen from 104 to 86."

From this time he has had no bad symptoms, and he is now convalescent, and may leave the hospital in a day or two.

Such is the case on which I propose to found some remarks on the nature and treatment of asthma: and first, as to the nature of this disease.

What is asthma?—I shall answer this question by stating first that it cannot be properly called a disease of the lungs—in other words, its primary seat is not in the lungs: it may be defined to be a constitutional disease, which manifests itself by paroxysms of difficult breathing, with intervals of various duration, in which the patient is completely or nearly in a healthy condition.

Let us look at the more prominent points in the clinical history of asthma, and inquire how far we may found upon them an explanation of its pathology.

The way in which the uncomplicated asthmatic attack commences is generally this. A patient, we will say, goes to bed quite well: soon afterwards he finds a difficulty of breathing come on; he cannot lie down; he cannot

go to sleep; the dyspnoea increases, and the attack becomes confirmed: or, what is very often the case, he goes to sleep quite well, and wakes in an hour or two with the attack on him. When ones formed, the asthmatic paroxysm continues for some time, and passes off generally with some cough and expectoration, but sometimes without either. The time of its duration is very variable: sometimes it lasts only a few hours, sometimes many days.

When suffering from the attack the patient cannot lie down. All asthmatics show an instinctive repugnance to the horizontal posture while the attack is on; and even in the intervals of the attacks they like to lie high, and seldom lie quite flat: generally they are content with sitting up in bed or on a chair, or they may sometimes move about the room. The coachman of a neighbour of mine some years ago suffered so much from a paroxysm of asthma, which resisted all treatment, that he was obliged to stand leaning forward on a table for three days; and in this erect posture he passed the whole of this time: at last he became so exhausted that he was obliged to sit down from sheer inability to support himself. The erect or semi-erect posture is no doubt preferred because it enables the muscles of respiration to act with greater freedom, and with more mechanical power.

These attacks are very much influenced by weather, particularly cold and damp, and by locality, as high or low, humid or dry, relaxing or bracing: and there is a remarkable capriciousness in these respects, some persons liking a low, damp, smoky situation, some a high, dry, and clear; that which is fatal to one case will be the very best thing to another, and one person will be well where another cannot live. Sometimes persons living in London, and wishing to try the neighbourhood, will ask you, "Shall I go to Clapham, or shall I go to Highgate—will a high or a low situation be the best for me?" Now this is a question that it is impossible to answer with certainty; for very often that which would seem the worst will turn out the best. I have known asthmatics better on the banks of the Thames than anywhere else; on the other hand, I have known some greatly relieved by going to a high situation. Dr. Watson has some interesting remarks on this subject in his valuable Lecture on Asthma, and relates some curious cases in illustration of the uncertain influence of locality in checking or promoting the asthmatic paroxysm.

Then, sometimes we find that asthma is brought on by certain specific irritating agents. We all know of *hay-asthma*: that if certain individuals venture within the

range of a hay-field, they are seized with sneezing, coryza, profuse lachrymation, and other symptoms of irritation of the mucous membrane, accompanied with a distinct asthmatic paroxysm. Similar symptoms are brought on in other people (but such persons are much fewer) by the volatile effluvia of ipecacuan, or by the presence of very fine particles of dust floating in the atmosphere.

Persons having had this disease for many years may cease to have any attack. I have known many cases of men and women who have lost the disease as they advanced in life. Now, in such cases of recovery, does the disease leave the lungs perfectly healthy? Not unless the attacks of asthma have been mild, and few and far between. Although not necessarily originating in the lungs, the frequent repetition of the asthmatic paroxysm doubtless always leaves some injury to the lung after it, which is the greater in proportion as each paroxysm is longer and more severe.

In asthma the respiratory efforts are greatly exaggerated, in consequence of the increase of the sensation of the want of breath—the *besoin de respirer* of the French; a sensation which any one may easily experience in his own person by simply putting his face into water for a few seconds. Under the influence of this strong feeling of the want of breath, large quantities of air are drawn in, and so great is the effort of inspiration that the noise which it occasions may be heard for a considerable distance. What results? The air-cells of the lungs become dilated, and the whole lung experiences a proportionate enlargement, and the external configuration of the chest is altered. This is well exemplified in our patient Shaw: he has a large, barrel-shaped chest, rounded in front, behind, and at the sides; and, if you watch him breathe, you will see that there is less movement at each respiratory act than there should be; the chest is in a state of permanent dilatation, the ribs are too horizontal, the intercostal spaces too wide, and the accessory muscles of respiration are always more or less in a state of action. The state of lung which is produced by asthma is that which has been called by Laennec *emphysema*—a name not happily chosen, as it implies what really does not exist, namely, the infiltration of the lung with air, the existence of air in its extravascular tissue. If the asthmatic attacks continue for any great length of time, and are severe, we find further injury of the lung taking place; the walls of the air-cells suffer in their nutrition, and some of them, already dilated to their utmost extent, give way; three or four, or more, become fused into one, and form large irregular cavities,

which are distributed among the healthy pulmonary tissue.

But, besides these changes in the lungs, the repetition of the asthmatic paroxysms leads with equal certainty to morbid changes in the heart. From the obstruction that is offered to the circulation through the lungs an undue amount of work is thrown on the right ventricle, which of course becomes more or less hypertrophied; at the same time the meshes of the pulmonary capillaries become enlarged, and no doubt experience some change in their vital properties whereby the circulation in them is retarded. This affords an additional means of obstruction through the lungs, and therefore an additional cause for hypertrophy of the right side of the heart. But as the backward pressure of the blood on the heart becomes increased, the right ventricle becomes not only hypertrophied, but dilated, and the dilatation extends in a retrograde course to the auricle, and thence to the large veins, so that in the advanced stages of this disease it is not uncommon to find venous regurgitation, and more or less congestion, throughout the whole venous system. In the early stages, however, none of these conditions will exist. You may have the most exquisite asthmatic dyspnoea without its leaving any perceptible deviation from the healthy standard either in the heart or lungs, or at most no more than may perfectly recover itself when the paroxysm passes off. This is more likely to occur in children, because their tissues have a greater power of recovery from their greater activity of nutrition.

Such cases as these would alone be sufficient to prove that asthma is a disease essentially independent of any organic lesions of heart or lungs, though frequently accompanied by them, aggravated by them when they exist, and always inducing them if it is of sufficiently long continuance. And it is remarkable how soon these lesions may be thus induced, how short a continuance of asthma will be sufficient to give rise to evident signs of organic change in the heart and lungs. Our patient Shaw had had asthma not quite three months, and for the greater part of the time not severely, and yet we find him with a barrel-shaped, unnaturally resonant chest, dilated thoracic parietes, and the heart so displaced and dilated in its right cavities as to beat in the region of the scrobiculus cordis.

I look upon this last sign as one of the most characteristic symptoms of asthma, and I consider its presence in any case where I suspect asthma, as a clear confirmation of the correctness of those suspicions. In accordance with this view, in examining a patient whom I suspect to be asthmatic, one of my first steps is to apply my finger

to his scrobiculus cordis: if I find no beating of the heart there, my conclusion is a contingent negative; but if I find it beating there; and not in its natural position under the nipple, my conclusion is a certain affirmative.

If you trace up the disease to the point of its first appearance, you will generally find that the first attack came on either without any assignable cause, or after some indiscretion as to diet—or after some imprudent exposure to weather; the patient went to bed well, and in every respect in his usual health, and woke up asthmatic,—but once having made its appearance, it renders its victim ever after liable to its recurrence.

A remarkable circumstance is, that it is often inherited; the father or mother have had it, or it may have left over a generation;—the grandfather may have been asthmatic, and the intervening generation not so. Once that the asthma has fairly established itself in any individual, it may be brought on by any slight cause, even the most trivial disturbance will be sufficient to excite it,—catarrh, indigestion, irregular hours, mental excitement, violent exercise, change of temperature, change of place—any one of these may bring on an attack. Now, if you inquire narrowly, you will generally find at the root of the disease some fault in the primary assimilation: you will find that the patient has learned to avoid certain things; that he is not at liberty like other men; there are some things of which he dare not partake, or, if he does, it is done at the price of an attack. And you will likewise find, on looking into the patient's secretions, that they are altered, that the urine is lithic, phosphatic (most frequently the former), or presents some deviation from the healthy standard. Very often, too, you will find the attack ushered in by a peculiar condition of the urine, either such as I have just mentioned, or urine resembling nervous hysterical urine, abundant, clear, and pale, and of very low specific gravity.

Now all these points,—the periodical recurrences of the attacks, the perfect, or nearly perfect health in the interval, the absence of any organic change, the associated humoral disturbances,—all bear in the most interesting way on the pathology of this malady. They tend to establish a remarkable analogy between asthma, gout, and some other diseases. As in asthma, gout comes on quite suddenly—there is no warning: a man may go to bed quite or nearly well, and he will wake up early in the morning with a fit of the gout in his great toe. There is another disease, epilepsy, in which we have exactly the

same phenomenon: a patient, with or without warning, falls down foaming, livid, and convulsed; the paroxysm goes off, and leaves him in his ordinary good health, and he may go on for years and not have another. Again, we know that a fit of the gout leaves no organic lesion if it occurs once or twice; but if it is often repeated it leaves permanent injury in the joints that it attacks. We may observe the same with respect to epilepsy. If a patient has suffered only one or two attacks, you will find no change in his brain; but if he has had several, you will. The disease evidently consists essentially of something *attracted* to the brain, and not *existing* in it. The same, too, of asthma, the organic changes are all secondary, and a few attacks leave no traces behind them.

All this leads us to suppose that the paroxysm of asthma has something in common with the paroxysm of gout and the paroxysm of epilepsy. Of the two I prefer to take the analogy to gout, because we have more definite and coherent ideas about gout, and we are more acquainted with its exact pathology. The theory at present most in favour with regard to gout is that it is a disease of assimilation, and this defective or vitiated assimilation gives rise to some *materies morbi*. When this matter is eliminated from the system, the attack passes off; when it accumulates, the attack comes on. In asthma defective assimilative power is a frequent coincident. Gout, too, and rheumatism, and all humoral diseases, resemble asthma in being inherited.

When the *materies morbi* of asthma has been generated its effect is to irritate the nervous system, not generally, but certain parts of it, those parts being the nerves concerned in the function of respiration—viz., the pneumogastric, and the nerves that supply the expiratory muscles, either at their peripheral extremities, or at their central termination in the medulla oblongata and spinal cord; extreme difficulty of breathing is the result, and, as a consequence of this, ultimate disease of the lungs.

Thus the occurrence of asthma in paroxysms would be accounted for much in the same way you would explain the occurrence of gout in paroxysms; and in the intervals between the attacks, the patient, being of asthmatic constitution, so to speak, is easily thrown into the paroxysm of asthma by causes which would but slightly influence other men,—as cold, impure air, mechanical irritation of the respiratory passages,—just as gouty men may readily be thrown into the gouty paroxysm by causes comparatively trivial.

This seems to me to be the most reasonable exposition of the pathology of asthma.

Now we often hear physicians of great and deserved repute speaking of *spasmodic* asthma. I need not tell you that the bronchi possess a muscular coat, consisting of circular fibres of the unstriated for it has been long proved, not only by microscopical observation, but by the most satisfactory experiments. It is in these circular muscular fibres of the bronchi that many pathologists localize the spasm, to which they ascribe all the phenomena of asthma.

The first link in the chain of effects of the immediate exciting cause of asthma would be, according to them, spasm of the bronchial tubes, then dyspnoea. Undoubtedly a state of spasm of the bronchial tubes would produce a great deal of dyspnoea; but what I want to point out to you is, that this state of spasm of the bronchial tubes ought rather to be regarded as one of the accompaniments, one of the phenomena of asthma, than as its cause. The feeling of breathlessness, or, in other words, a peculiar state of certain nerves and of a certain nervous centre, the centre of respiration, is the first link in the chain of asthmatic phenomena. The spasm of the bronchi follows sooner or later upon this, and often it follows so quickly upon it as to appear to come simultaneously with it: does it ever precede it? I doubt this.

Undoubtedly you may have severe asthma without severe spasm of the bronchial tubes. I remember a well-marked instance of this in a gentleman whom I attended for chronic disease, cancer, as I thought, of the liver. For nearly a week before his death he suffered from the most frightfully distressing asthma, which nothing could control, and which lasted without interruption till he died. I examined his chest repeatedly at all parts, and could hear nothing but the most perfect, loud, and puerile breathing, which is quite inconsistent with a state of spasm.

Again; section of the vagi nerves of animals produces phenomena exactly like those of asthma. Whatever be the cause of the dyspnoea in these cases, it is clear it cannot be bronchial spasm, as the muscles of the bronchi would be paralysed after section of their nerves.

There is one thing that I have observed, which has an important bearing on this subject; that in that particular form of spasmodic disease which I have no doubt in your future practice you will have many opportunities of witnessing, laryngismus stridulus, the crowing inspiration of children, there is a ronchus all over the chest, simultaneous with the convulsive attack.

The moment the convulsion comes on, when the eyes become fixed and the child begins to inspire with difficulty, if you put your ear to the chest you will hear a ronchus pervading the whole lung. The moment the recovery takes place, the ronchus ceases. And it is very interesting to notice that you may observe the very same thing in the ordinary convulsions of children, in which the larynx is not prominently engaged; and I suppose no one will pretend to locate these diseases anywhere but in the nervous system.

Hence the conclusion that I draw is this, that the spasm is the accompaniment, and not the cause of the difficult breathing that accompanies or follows upon the nervous changes, just as it does in laryngismus and in the ordinary convulsions of infants.

So much for the pathology of asthma; as to the treatment of this disease our attention must be directed

1. To obtain relief to the paroxysms, and
2. To improve the patient's constitution in the intervals of the paroxysm.

First, in the asthmatic paroxysm you must inquire into the immediate exciting cause, and endeavour to remove it. With this view an emetic, by emptying the stomach, will often be found useful; or if the quality, not the quantity of the contents of the alimentary canal is the source of the evil, an alkali will be found beneficial. Stimulants are sometimes of essential service, especially when the long-continued circulation of imperfectly arterIALIZED blood has deadened the sensibilities, and so far lowered the powers as to render the expectoration of mucus difficult: one of the best stimulants is sulphuric ether, or perhaps the chloric is even better, from its taste and smell being so agreeable. Ether, in combination with opium, will often be found of great service. But perhaps the *sedatives* constitute the class of remedies that has met most favour in the treatment of asthma, and especially the different members of the order *Solanaceae*,—as *Hyoscyamus*, *Belladonna*, *Tobacco*; but before and above all, both in the frequency of its employment and its real value, *Stramonium*. This medicine may be given in various forms,—as an extract of the seeds, in doses of from gr. $\frac{1}{4}$ to gr. $\frac{1}{2}$, or in the form of a tincture, in from ten minims to half-drachm doses; but more frequently it is smoked, and for this purpose the whole plant, leaves and stems, are used; it is dried and cut into small pieces, and smoked in a pipe, or the leaves alone are dried, and rolled up in the form of a cigar. I here show you some of these cigars, which have been put into my hands by Mr. Sa-

vory, of Bond Street; but I must tell you that these are not, strictly speaking, *Stramonium* cigars, being made, not of the *Datura Stramonium*, but of the kindred species, the *Datura Tatula*, which is said to be even more efficacious than the more generally used species.

Lastly, we find a valuable remedy for the asthmatic paroxysm in chloroform: we know how in other cases it influences all those functions which are ministered to by nervous influence, and in its efficacy in asthma we have an interesting physiological experiment, and an important lesson with regard to the true pathology of the disease. But in the administration of chloroform I would give you this two-fold caution:—first, to give it gradually and cautiously, and not in a full dose; not to produce insensibility, especially if there be anything like blueness of the surface, because, though remedial to the asthma, it will tend to increase those very consequences which are most to be feared from the circulation of venous blood. Secondly, to impress upon your patient that he must never give it to himself, nor without the presence of a medical man. This case was related in the papers the other day: A person who was in the habit of curing his attacks of asthma by inhaling chloroform, when administering it to himself one day, and when in a state of half subjection to its influence, to produce the full effect placed his handkerchief on the table, and buried his mouth in it; his insensibility became deeper and deeper, till at last he was too far gone to be able to raise his head. He therefore continued inspiring it, his coma became more and more profound, and a short time after he was found in that position, quite dead.

Secondly, the treatment in the intervals between the paroxysms should be directed to improve the digestive powers of the patient and the tone of his nervous system; the diet should be very carefully regulated, both as to nature and quantity; and this is of all things the most important to occupy the attention of the medical attendant. The alimentary canal and the secretions generally should be kept in a healthy condition; exercise, the hours of rest, and in fact every thing that bears on the general health, should be systematically and rigidly superintended; and I am sure that treatment of this sort will always be found of substantial advantage. Another thing having the same object is cold or tepid affusion, either by sponging or by shower-bath: but cold, while very serviceable to those who can bear it, is often too much for many people, in whom no reaction takes place, the coldness continues, and drowsiness is produced. Such symptoms should always be looked

upon as contra-indications to the use of cold affusion.

Now before I conclude, I will say a word on the relation of emphysema and asthma. Are these two diseases related to one another as cause and effect? and, if so, which is the cause, and which the consequence? To determine this let us see what emphysema is. It is a state in which the lungs are rendered more capacious, in which the relation of the ultimate elements of the lungs are in some measure deranged, and the pulmonary capillaries altered. Now, is this state of increased capacity a state capable of producing such a dyspnoea as we see in asthma? I cannot think that it is, although this increased capacity is attended with other conditions tending to diminish the efficient aeration of the blood, and, therefore, to the production of dyspnoea. But it will not explain the periodicity of the attack: emphysema is constant, asthma paroxysmal. On the other hand, asthma is clearly an efficient cause of emphysema; the asthmatic condition is just such as to produce those physical changes that constitute emphysema; and I think that all patients who have emphysema have had either asthma or bronchitis. It is confirmatory of this view, that emphysema comes on gradually, and that it bears proportion to the length of duration and severity of the asthma; if a person has had few attacks of asthma he has no emphysema, if he has had many, he has; the asthma precedes, the emphysema follows.

This then is the conclusion I come to,—that asthma is primarily humoral; that it is caused by a poison or a morbid matter acting on that portion of the nervous system which ministers to the function of respiration; that it leads to dilatation of the lungs and the walls of the chest, to emphysema, and ultimately to dilatation of the heart; that the habit may pass off, the morbid matter being no longer created, the patient ceasing to be asthmatic, just as a person ceases to be gouty or epileptic; and that, ceasing to be asthmatic, the patient may remain, or may not remain, emphysematous, according to the severity and duration of his previous attacks.

THE CHOLERA IN JAMAICA.

By intelligence from Kingston to the 8th ult., cholera continued to rage with great violence all over the island: the deaths in Kingston alone, from October 10 to November 7, were 1,000. Business was all but suspended. The weather had been highly favourable for the suppression of the disease.

Original Communications.

CASES, WITH REMARKS, ILLUSTRATING THE ASSOCIATION OF CHOREA WITH RHEUMATISM AND DISEASE OF THE HEART.

By WILLIAM SENHOUSE KIRKES, M.D.

Licentiate of the Royal College of Surgeons; Demonstrator of Morbid Anatomy, St. Bartholomew's Hospital.

(Read before the Abernethian Society, March 7th, 1850).

For some years past attention has been frequently directed to the occurrence of various nervous phenomena, especially of chorea, in the course of acute rheumatism. The subject has engaged the notice of those best qualified for its investigation, and several ingenious hypotheses have been advanced in explanation of this singular association in disease. To the complete exposition of the views of those who have especially studied this point in pathology, given by Dr. Burrows in his Treatise on Disorders of the Cerebral Circulation, it will be needless, even were it possible, to attempt making any addition: indeed, the subject is so thoroughly discussed there, and in the works therein mentioned, that, but for the obscurity in which the association between the rheumatism and the nervous phenomena is still confessedly involved, I should not feel justified in again drawing attention to it. The very variety of the explanations which have originated from equally competent sources, bears ample testimony to this obscurity on the subject; and on this account it may be hoped that any additional facts which seem calculated to throw light on any part of it can scarcely be deemed superfluous.

The cases and remarks which I now offer have reference to only one form of the nervous disorders that may arise in the progress of acute rheumatism, and this because it is the form most apt to ensue, and because I am more familiar with it than with any of the other affections of the nervous system associated with this disease.

CASE I.—Mary Anne Burke, aged 20.

admitted into Hope Ward, under Dr. Hue, Dec. 3, 1849. Dark-haired, pale, anæmic-looking; manner strange, with an anxious alarmed expression. There were frequent spasmodic movements of the muscles of the face, especially about the nose, these movements being usually accompanied by a short inspiratory moan. These, with an occasional jerk of her head, were the only choreic movements observed. Although involuntary, yet the movements seemed to be under some degree of control; for, by an effort, she could restrain them for several seconds, though after such pause they returned with increased force. She was very taciturn, owing apparently to difficulty in uttering words rather than to disinclination to speak: her answers, when obtained, were rational and correct. She said that she was in pain all over, especially in the ankles, knees, and hips. The left ankle and foot were slightly swollen and tender, but not red.

I may remark here that this slight swelling and tenderness, which shortly disappeared, was the only positive sign, in addition to the general complaint of pains in the joints, that acute rheumatism existed: it was, however, quite sufficient to denote the fact. There was a dry black secretion about the lips; the tongue was pale, thickly furred white, with a dry brown streak down the centre, spreading out at the apex. The pulse was 84, but singularly irregular,—usually three beats would occur in ordinary succession, then there would be a complete intermission, then three more ordinary beats, followed by another intermission. She passed her evacuations in bed, but was conscious of doing so.

She was a dressmaker, always delicate, and subject to severe headaches, especially since a violent blow on the head six years before. She never had rheumatism or chorea; but her mother was rheumatic, and a sister had been in the hospital with rheumatic fever. Nine days before her admission she began to be ill, chiefly with palpitation and a feeling as if "something was amiss with her heart." Three days subsequently she came to the hospital to have a tooth extracted; it was then noticed that her throat was inflamed. At this time her catamenia, which had hitherto been regular, were due, but they did not appear. The next day her throat was

worse, with increase of palpitation and pain in the chest. The twitchings of the head and face commenced two days before admission. For several nights she had had no sleep, and latterly had been delirious, and with difficulty kept in bed.

On auscultation there was found to be increase of the heart's impulse, which was perceived over a greater space than natural. The first sound was loud and ringing, with a short blowing murmur at the apex; the second sound indistinct. There was increased and extended cardiac dulness on percussion. This auscultation was made a few hours after her admission into the hospital; but, when first admitted, certain sounds were heard which led my friend Mr. Wood, who then examined her, to suspect the existence of pericarditis. These sounds, however, had quite disappeared on the subsequent auscultation.

There was something in the general appearance of the patient which suggested the possibility of many of her symptoms being the result of hysteria, and she was accordingly treated at first with the *Haust. Ammoniaci Fœtidus*. The day following, however, the irregular movements had extended to the shoulders, and the next day both arms were affected, the general and auscultatory signs being otherwise unchanged, except that the pulse had become regular. During the night of December 5th, which was her third night in the hospital, she was noisy and delirious, but when visited the following morning was found calm and rational, though with a haggard anxious aspect. The spasmodic movements of the arms were increased in violence, and the right lower extremity was now affected. The lips were dry; tongue red, glazed, and clean, but inclining to dry; skin cool; pulse 120, small, soft, regular: the bowels, which had been relaxed, were quiet: she complained of thirst, headache, and a feeling of weariness and exhaustion; the heart's impulse and action were much increased, and the first sound was prolonged, muffled, and accompanied with a murmur.

Her hair was ordered to be cut short behind, and a blister applied to the nape of the neck, on the supposition that there was some mischief in the head.

The two following nights she had a little rest, and the involuntary movements of the limbs did not increase in

violence, but her peculiar anxious haggard look remained. On the night of the 8th (five days after admission) she was again restless and delirious, and on the following day the chorea had greatly increased, the arms and head being continually tossed about, and the shoulders and chest writhing and twisting incessantly. She got a little sleep in the morning, but was no better on awaking. The jactitation increased towards night. Chloroform was then administered, and quieted her for a time; but, as the effects of the reagent passed by, the movements returned with the same violence as before. On the 10th I made the following note:—With exception of an occasional doze, she was restless and tossing about all night, frequently uttering short spasmodic screams; is now in a state of constant restlessness and jactitation, throwing her arms about, and tossing her head from side to side, the legs being nearly still. She tries to speak, but cannot, only uttering unintelligible sounds: she also frequently attempts to cough, but fails in the effort, apparently from inability to combine the requisite muscular movements. Face pale and haggard; lips covered with sordes; tongue brown and dry; skin cool, moist: pulse small, feeble, about 120 in the minute, her restlessness preventing its being accurately counted. The like cause also interfered with a proper auscultation of the heart. Her head was again shaved, and a blister applied to the vertex. She also took chloroform again with temporary cessation of the movements, followed by a little sleep. She appeared to like the remedy, and occasionally asked for it, as well as she could. In the evening and early part of the night she had a little sleep, but after two o'clock the following morning the choreic movements became more violent, involving the lower limbs, and increased to such a degree that it became necessary to tie her in bed to prevent her being thrown out. Between nine and ten o'clock she was lifted out of bed to have her bed made and her blister dressed. On being returned to her bed, she took eagerly about half a pint of beef-tea, then lay quiet, and in a quarter of an hour was dead.

Five hours after death the brain and heart were examined. In the former, nothing unusual was noticed beyond a peculiarly soft condition of the cerebel-

lum. In the latter was found the probable source of all the mischief. The two surfaces of the pericardium were universally and rather firmly adherent to one another through the medium of a thin layer of soft, reddish, rather dry granular lymph. The heart was rather large: its muscular tissue presented extensive fatty degeneration, large buff-coloured blotches being abundantly scattered through the walls of both ventricles, while the interior of these cavities exhibited in an extreme degree the peculiar streaky, freckled aspect, so characteristic of fatty disease of the heart. Moreover, there was abundant evidence of recent endocarditis, the tricuspid, mitral, and aortic valves being more or less thickly set near their free borders with clusters of minute, soft, reddish, loosely adherent granules.

The objections of friends prevented the spinal cord and other organs from being examined. The liver, however, was noticed to be extremely fatty.

Here we have a case in which a delicate girl, inheriting a tendency to rheumatism, and having a sister formerly affected with that disease, becomes out of health just at a period when the catamenia are expected, but do not appear, suffers a slight attack of articular rheumatism, with a severe inflammation of the investing and lining membranes of the heart, and then has violent chorea, which terminates in death, dissection disclosing, moreover, extreme fatty degeneration of the muscular tissue of the heart. Abundant matter for general comment is here offered, but into this we must not now enter.

CASE II.—Ann Holt, aged 13, a thin, light-haired child, admitted under Dr. Roupell, October 18, 1849, with rheumatic inflammation of various joints, of five days' standing, and pain in the chest of one day's duration. The heart's action was accelerated, and there was a prolonged soft systolic murmur at the apex, faintly heard also at the base, where the second sound was clear. So far the mischief seemed to be only endocardial. She was treated by leeches to the region of the heart, and small doses of calomel and opium every four hours. The next day (the 19th) the first sound at the apex was confused, while at the base a peculiar creaking sound was audible with the systole, the second sound still remaining clear. On the

20th, the joints being still very bad, the first sound continued rough and crackling at the base, while a somewhat similar sound was occasionally audible with the diastole. Little doubt now remained of pericarditis being superadded to the endocarditis, and this little was removed by the pericardial friction becoming more distinctly marked during the next three days, and then it disappeared, leaving an endocardial systolic murmur both at apex and base. The rheumatism now rapidly subsided, and the child got so much better, that I took no further note of her until the 29th, five days after the disappearance of the pericardial sounds. On this day I learnt that the preceding evening she was observed to be very strange and foolish in manner, and that subsequently twitchings ensued in the face and arm: she passed a restless night, and in the morning she had frequent spasmodic movements of the muscles of the face, with involuntary knitting of the brows, while the left hand and arm were constantly in movement. Her thin, wan, feeble aspect, was even more striking than on any previous occasion, and was now combined with an expression of alarm at her strange condition. On auscultation the systolic murmur remained loud, both at the apex and base, while over the aortic valves was heard, for the first time, a remarkably harsh and prolonged diastolic murmur. Her feeble condition, with a small pulse of 130, precluded any active measures, and she was treated simply with Dover's powder to tranquilize her nervous system.

Without going into the daily particulars of this case, I will just remark that the chorea did not materially increase, and scarcely lasted three weeks. During this period there was no return of the pericardial rubbing sound, but the endocardial murmurs underwent strange varieties, which, however instructive in themselves, may be at present passed over, as not bearing materially on the question before us. The child left the hospital shortly after the subsidence of the chorea, but carried with her all the signs of seriously damaged mitral and aortic valves, with an enlarging heart, and probably some remaining mischief in the pericardium. In less than three months she was re-admitted in a dying state, with symptoms all pointing to the damaged heart and secondarily damaged lungs. At first she rallied, and for

some days gave promise of amendment, but then she worsened and died, a copious pleuritic effusion appearing to be the immediate agent in her death. The examination of the body after death revealed recent inflammation of the right pleura, with pneumonia passing on to suppuration. The heart was considerably enlarged, while the effects of the former inflammation were manifest on the mitral and aortic valves, and on the interior of the left auricle. The condition of the pericardium was examined with peculiar interest, on account of the pericardial friction-sound which was noticed about four months before her death. The only evidence of the previous inflammation was in the existence of numerous vascular tufts of new tissue about the base, and of several rough vascular patches of false membrane on the anterior surface of the heart. I have alluded to this case before, in support of the opinion I entertain, that inflammation of the pericardium attended by effusion of lymph does not necessarily terminate, as is commonly supposed, in the formation of permanent adhesions.*

CASE III.—The next case I wish to mention is that of a girl named Eliza Blanning, aged 13, who was admitted January 31, 1850, under Dr. Hue, with acute rheumatism and serious cardiac complication. This girl had been in the hospital two years previously with a somewhat similar attack, and then fell under the notice of my friend Dr. Ormerod, from whom I learn that she was admitted simply for chorea, that subsequently pericarditis ensued, and then, last of all, a distinct attack of articular rheumatism came on. The ordinary sequence of events was therefore, in this case, completely reversed; and the fact is one of importance in relation to the probable cause of the association of chorea, and other nervous diseases, with rheumatism. Another fact bearing on the same subject is, that this girl had suffered at least two, if not three previous attacks of chorea, unassociated with rheumatism, or other obvious cause—the first when she was nine years old, the second shortly afterwards. I need not dwell on any further particulars of the case during her present visit to the hospital: suffice it that, after being placed in ex-

treme jeopardy by the cardiac affection, she was discharged convalescent, though with a seriously and permanently damaged heart. During this attack there was no return of the chorea.

In each of the three cases I have just narrated the rheumatism and chorea were distinctly associated with pericarditis; but I will now mention other cases in which there was reason to believe that the pericardium was quite unaffected, while in at least one case it was probable that there was no affection of any part of the heart.

CASE IV.—In November, 1849, William Harvey, aged 20, a tall, dark-haired, nervous man, was admitted, under Dr. Hue, with a second attack of articular rheumatism, unaccompanied by cardiac affection. Ten years previously, when he was therefore 14 years of age, he had his first—a very severe attack. In the course of it chorea ensued, and lasted several months, at the end of which time he left the hospital well: he had no reason to suspect that his heart was affected during this attack, having no symptoms referable to that organ at the time, and not having been subsequently troubled with palpitation. On his second admission to the hospital the attack of rheumatism was severe, though less so than the former attack. I carefully examined his heart from time to time during the progress of the disease, but never could satisfy myself that there was anything morbid in its sounds or action beyond increased impulse, which might be explained by the general vascular excitement attendant on an acute febrile disorder. It is certainly possible that, in the first attack of rheumatism, there might have been inflammation of the pericardium, resulting in partial adhesion of the pericardial surfaces, and that, in this second attack, pericarditis may have again ensued, and its existence been undetected, owing to absence of the pathognomonic friction-sound in consequence of such adhesion. Yet this can only be supposition; and, in the absence of stronger evidence of pericardial inflammation, it is, I think, fair to infer that the pericardium was unaffected in this second attack. After being in the hospital for about five weeks, and when the rheumatism had almost subsided, chorea again came on, and gradually increased until it had attained such a degree of violence

that the man had to be kept strapped down for a week, to prevent his being tossed out of bed. During the chorea his heart was again several times closely examined, but nothing morbid was detected; and, when he was so far recovered as to be discharged from the hospital, the sounds were quite those of health. The nervous affection in this case seemed therefore to be unassociated with any affection of the heart.*

The following case may be mentioned as somewhat parallel to the last, though it is open to the objection that there was no auscultatory proof of the pericardium or the heart being formerly unaffected.

CASE V.—Elizabeth Lark, aged 17, a healthy-looking girl, was admitted February 1st, 1849, under Dr. Burrows, for a rather slight attack of chorea, of a fortnight's duration. The catamenia were regular, the heart's sounds perfectly healthy. She had had four or five similar attacks; the last occurred when she was 14 years of age, and after continuing for two or three weeks it was followed by a severe attack of articular rheumatism, which confined her to bed for fourteen weeks, the chorea continuing nearly the whole time, and greatly aggravating her sufferings, by the constant movements of the inflamed joints. She had at that time no pain about the chest, and was not subsequently troubled with palpitation.

As before stated, however, these negative circumstances cannot be held as certain evidence that there was at that time no affection of the heart: such affection might have existed, and subsequently quite disappeared, supposing the pericardium to have been inflamed in that attack. We must, however, in such case, conclude, either that no pericardial adhesion had resulted, or, what is not probable, that an adherent pericardium existed, without manifesting any general or physical sign of such a condition.

It may be observed, that in this case, as in Case III. the chorea preceded the rheumatism; also that there had been several previous attacks of chorea, unassociated with rheumatism: the import of these facts will subsequently appear.

* In two months afterwards, however, this man was re-admitted with another attack of rheumatism, followed again by chorea, and accompanied this time with a rough systolic murmur at the apex.

CASE VI.—Maria Potter, a healthy-looking girl, 16 years of age, was admitted under Dr. Burrows with rather a severe attack of chorea, from which complaint stated she had scarcely been free since she was six years old. When fifteen she was in St. Bartholomew's Hospital with acute rheumatism; she then had a slight attack of chorea; the catamenia first appeared at that time. She had been troubled with palpitation since the rheumatism. When in the hospital the second time, the chorea was not associated with rheumatism: there was, however, a soft systolic murmur at the apex, which seemed to indicate that in the previous rheumatism she had suffered from endocarditis. There was, however, no evidence of previous pericarditis; and the remarks on this point applied to the last case will apply here also.

CASE VII.—Eliza Fanchild, aged 17, a small, puny, undeveloped girl, who had never menstruated, was admitted under Dr. Roupell, with a severe and first attack of chorea, which could not be traced to any exciting cause. There was no rheumatic history; and I could not clearly ascertain that she had been particularly exposed to fright, which is so often the alleged, and probably the real, exciting cause of chorea. After about six weeks of incessant choreic movements, terminating at last in complete jactitation, requiring her to be restrained in bed, the poor girl died, quite worn out.

After a careful post-mortem examination of the body, including the brain and spinal cord, I could find nothing at all bearing on the case, except that the free edge of the mitral valve was roughened by minute granulations.

Apart from the general interest which this case possesses as an example of fatal chorea, in which examination after death failed in disclosing any serious organic lesion, the case is of pathological value, from the presence of the deposits of fibrine on the mitral valve: the bearing of this point on the subject under consideration will appear in a subsequent part of this communication.

[To be continued.]

AN ESSAY ON UNHEALTHY INFLAMMATIONS.

BY M. BROKE GALLWEY, ESQ.
Assistant-Surgeon Royal Regiment of Artillery
Woolwich, Kent.

[Continued from p. 796.]

ERYSIPELAS (continued).

Question of treatment continued—Heat and redness no criterion of power—Opinions of those writers who regard it as an asthenic disease—Illustrations of the views and arguments upon which they are founded.

"PARACELSUS declared to his audience, that if God would not impart the secrets of physic, it was not only allowable, but even justifiable, to consult the devil." It is much to be desired that practitioners in medicine, in our own time, would leave this latter alternative to the disciples of Mesmer and of Hahnemann, and to impostors of this stamp; and that, if resolved to persist in bleeding their patients *by the bucket*, they would be content to register their heroic deeds on the tablet of their own consciences, in place of recording them in print, to the irreparable injury of the rising generation in the profession—not to speak of the additional labour thereby indirectly thrown upon the hands of the already hard-worked registrar of mortality.

The mistaken and mischievous principle of seizing upon a particular *quality* in disease—as the "rubor," the "calor," or the "tumor"—and setting that up as the all-absorbing feature in its pathology, was well remarked upon two hundred years ago by Sydenham. In treating of gout, our illustrious countryman says—"He has the best and truest claim to the name of physician who is in possession of the medicine that shall destroy the *species* of the disease—not he who merely substitutes one primary or secondary quality for another. This he can do without extinguishing the species at all—i. e. a gouty patient may be cooled or heated, as the case may be, and his gout continue unconquered. This method of merely introducing different qualities can no more effect the direct destruction of specific diseases, than a sword can quench a flame. What can be done by cold, or heat, or wet, or dry, or by any of the secondary qualities

that depend upon them, against a disease whose essence consists in none of them?*" The far-sighted sagacity discernible in this single remark bespeaks this wonderful man as a couple of generations in advance of the pigmies in learning of his time, and is so far deserving of note in our own day, that we are only just beginning to recognise these "qualities" in disease as consequences of a cause in operation elsewhere, and not as the primary elements of the same. But the great body of the profession is by no means prepared, as yet, to recognise the truth, that some of these qualities under notice—the "rubor, tumor, et dolor cum calore," more especially—are not the direct expressions or representatives of power in the circulation of the part where they occur. Hence, I conceive, the practical evils arising out of these misconceptions, and which, I think, are forcibly illustrated in the practice of Dupuytren, of Dr. Duncan, jun., and of Mr. Lawrence, as addressed to the heat and redness of erysipelas.†

As respects the increased heat of inflamed parts alone, it is becoming more probable every day, as Mr. Paget has lately suggested, that this phenomenon is rather significant of some combustion or destruction "of wasted tissues, or of surplus food," than of the "increased formation of organic substances." It is certain that heat is often developed in proportion to the decline of the dynamic powers of life. This was long ago alluded to by De Haen:—"Omnium maximus calor inventus est hominis, quo tempore cum morte luctatur, exspirat, jamque aliquantum vivere desinit; ita quidem, ut deprehenderimus, in ægro, cujus calor per totum acutum morbum supra 103. gradum non ascenderat, sub mortem, perque bina a

morte minuta, notari gradum caloris 106." And he gives us, amongst others, this striking example—"Mulier exulcerato mammae cancro misera, colore livida, omnino emaciata, pulsum parvum habens, tota die sedens, iterato quater spatio mensis experimento, constanter inventa est gradus tres quatuorve majoris, quam sano in homine est, caloris notare."*

Mr. Paget, in his recent lectures on *Inflammation*, has pointedly touched upon this question. "It may be said," observes Mr. Paget, "that the signs of inflammation are signs of increased action; but these are fallacious if, again, by increased action be meant any increased exercise of vital force. The redness and the swelling of an inflamed part declare the presence of more blood, but this blood moves slowly; and it is a quick renewal of blood, rather than a large quantity at any time in a part, that is significant of active life. An abundance of blood, with slow movement of it, is in no case characteristic of activity in a part; it more often implies the contrary, as in the erectile tissues and the cancellous tissue of bones. The sign of heat in the inflamed part is equally fallacious. The source of the locally-increased heat cannot, I believe, be satisfactorily explained. This phenomenon of inflammation is involved in the same difficulty as are all those that concern the local variations of temperature in the body,—difficulties which the doctrines of Liebig, however good for the general production of heat, are quite unable to explain. But, from the fact that the general supply of heat in our bodies is derived from oxidation or combustion of wasted tissues, or of surplus food, we may assume that in local augmentation of heat the source is rather from some similar destruction of organic substances than from increased formation of them. This can, indeed, be only assumed; but, if there be little evidence for it, there is as little for any assumption that the increased heat of an inflamed part is an indication of an increased formative action."‡

I have felt the more satisfaction with the embodiment of these views of Mr. Paget's, that they express so completely

* Preface to third edition: from the Latin of Dr. Greenhill, vol. i. p. 21. The italics are my own.

† The question should have been appended to the critique upon Mr. Lawrence's monograph in my last paper, but may not be wholly out of place in the present. For what object or end was Mr. Lawrence's paper published at all? Who were the committee or arbitrators legislating upon its merits? Surely, it is to be hoped that he was not the presiding judge himself, as in the late adjudication of the Swiney Prize! If not, the selection of a most pernicious as well as mediocre production for publication in the Society's Transactions, bespeaks, in my opinion, either a venal and corrupt state in the administration of that learned body at the time, or a lamentable want of intellect on the part of the "Committee of Papers."

* Rationes Medendi Antonii De Haen, caput "De Sanguine et Calore humano," tom. iii. p. 227-8. Vide also vol. ii. caput, "De suppartando Calore Corporis humani."

‡ MEDICAL GAZETTE for July 19, 1856, vol. xiv. p. 90.

those which I have myself long held* in connection with the interpretation to be put upon these physical qualities of redness, heat, &c., in the inflammations, but, for a clear exposition of which I had in vain looked through the literature of medicine; and, they are the more important, that the attention which these lectures are at present receiving at the hands of the profession may become the means of restraining the rising generation of surgeons from blundering on in the footsteps of their predecessors, even where great names may seem to invite a continued onslaught upon the *rubor et calor* with lancet, leeches, and Epsom salts.

Having afforded the reader an opportunity of forming an impartial opinion of the merits of those writings in the literature of medicine which are the advocates of a depletory and lowering plan of treatment for this disease, I crave his patient attention to the arguments which I now propose to bring forward in support of a directly opposite practice; and I flatter myself that he will find no fault with the authorities I shall cite.

"Sanguinis equidem missio," says Heister, "nec non alvi purgatio in erysipellate non æque ut in phlegmone necessariæ videntur. Quicquid enim in erysipellate mali corruptive humoris subest, id ipsum, quis in summâ tantum cute hæret, per sudorem lenem quam commodissimè expellitur." However, Heister makes this qualification:—"Interim, ubi vel nimis vehementes pulsus arteriarum et calor est, vel nimia quoque sanguinis eopia, haud omnino aliena sanguinis per venas detractio censenda est."†

"The erysipelatous inflammation," says Hunter, "often arises spontaneously, or in consequence of a low or debilitating fever. It often arises from accident, but then it is commonly a secondary inflammation, although not always; for, the first shall have gone off, and when suppuration was to take place it shall have come kindly on, but afterwards the erysipelatous shall take place."

* Vide a series of papers, by the writer, on "Unhealthy Inflammations," in the *Lancet* for 1849, *passim*. *Es. gr.*—"It is the crying sin of the present day to associate heat and redness, under whatever circumstances occurring, with a necessarily sthenic condition of the system."—*Lancet*, Nov. 24, 1849.

† *Institutiones chirurgicæ*, vol. i. p. 233.

"Whatever the inflammation may be" (meaning, probably, whether idiopathic or symptomatic), "it is certainly attended with nearly the same kind of constitutional affection. The fever in both appears to be the same—viz. accompanied with debility, languor, &c."

Hunter, in the foregoing paragraph, has been explicit enough in his opinion of the asthenic character of the disease; but we find him even more decided in these views elsewhere:—

"So far as it may be necessary to take notice of the different inflammations, they may be comprehended in *five* divisions." (I have already† individualized these, but should have added that this division is meant to be exclusive of the *specific* inflammations—such as gout, syphilis, &c.) "All except the first," (the "adhesive") "have a kind of *affinity to each other*, although I think the oedematous has the least affinity to the three last; and may vary so as to make it difficult to say to what species the varieties belong."

"All" (except the first)—"that is, the oedematous, erysipelatous, carbuncular, and the gangrenous—have a kind of *affinity to each other*."

Now, of the oedematous Mr. Hunter remarks—"The difference between this inflammation and the adhesive arises, I conceive, from the principle of inflammation acting upon a *dropical disposition, which is always attended with weakness*; whereas a greater degree of strength would have produced the adhesive inflammation under the same cause or irritation."§

Of the carbuncular he says—"This inflammation attacks more beyond the middle age than at it, and very few under it. It is most common in those who have lived well. It appears to have some affinity to the boil; but the boil differs in this respect—that it has more of the *true*" (healthy?) "inflammation, and therefore spreads less, and is more peculiar to the young than the old, which may be the reason why it partakes more of the true inflammation."¶ Had Mr. Hunter lived in our own day, he would, doubtless, have expressed himself far more decidedly upon

* Hunter's Works, vol. iii. p. 314-15.

† *MEDICAL GAZETTE*, p. 707, Oct. 25, 1850.

‡ Hunter, vol. iii. p. 316.

§ *Ibid.* loc. cit. p. 314.

¶ *Ibid.* loc. cit. p. 317.

the unmistakably *low* character of the carbuncular inflammation.

That Mr. Hunter considered his last form of inflammation—viz. “that which leads immediately to mortification”—as no exception, *in amount of power*, to the preceding, is evident from his own account of the matter:—“Inflammation often produces mortification or death in the part inflamed. This commonly takes place in old people that are become very much debilitated, and chiefly in the lower extremities. I suspect it to be somewhat similar to the carbuncle—viz. principally in those who have lived well, although not so much confined to them as the carbuncle: however, it takes place in the young where *great debility has been produced from disease, especially those diseases that have debility as a principle*—such as what are commonly called putrid fevers; but the situation of these is not so determined, and, in such, inflammation hardly takes place without an immediate exciting cause, as the application of blisters, &c. Death in a part sometimes takes place almost immediately without inflammation.”*

“Such inflammations,” adds our author (alluding to the four here particularized), “have little of the adhesive tuffaction in them, are not clear or transparent, but rather of a dusky red. As the colour of the inflamed parts shows something of its nature, it is to be observed that it is different in all these inflammations from that of the true adhesive; and, as we have reason to believe that the circulation is quicker in the adhesive inflammation than is natural, and that the colour arises from this cause, *we may suppose that the motion of the blood in these is languid, and that it assumes the venal appearance even in the arteries.*”†

It is with peculiar pleasure that I have been able to press Mr. Hunter into my service, in support of the existence of such forms of inflammation as are immediately dependent upon *asthenic* conditions, as this is the best commentary I could offer upon Mr. Lawrence's negation of the compatibility of such with debility.

I refer with scarcely less satisfaction, in the next place, to an authority of great weight with the profession in this

country, as he has thrown himself so unreservedly into that view of the subject in hand which I believe to represent the true nature of the pathology of erysipelas:—“I must acknowledge that a patient study of nature hath induced me to suspect that the *relation between erysipelas and inflammation is extremely remote*. It appears to me proper and justifiable to consider erysipelas as a genus, the specific characters of which are as widely differing from inflammation as those of inflammation are dissimilar from the phenomena proper to fever. This opinion will receive farther illustration if we advert to the mode of treatment that is appropriated to each; the very different manner in which the two diseases terminate; and also to this remarkable fact—that the two diseases are not reciprocally “converted into each other” (p. 174-5). That hardness of the pulse, which is a distinguishing character of inflammation, is not present in erysipelas. The general state of the system verges rather to debility, or depression of strength, than to increased strength or vigour.” And then Mr. Pearson adds the following proposition:—“In a part that is affected with an erysipelas there is a morbid irritability of the nerves; arterial contraction is performed with an increased velocity, but with diminished vigour” (the same conditions of arterial contraction, I may remark, which characterise the system under loss of blood); “and the parietes of the blood-vessels give less resistance than natural to the *vis à tergo*.” (p. 182-3.) It is no little detraction from these very sensible and satisfactory views in relation to the pathology of erysipelas, that Mr. Pearson, under the head of Treatment, directs his readers “to diminish increased vascular action in the acute erysipelas by general and topical blood-letting.” But he adds—“General bleeding is not recommended in this place as a cure for erysipelas in the same sense in which it may be said to remove an inflammation: it is advised with the intention of obviating the effects produced in the system by so severe a stimulus as acute erysipelas!” And then—“The exhibition of emetics and severe purgatives have sometimes been succeeded by very fatal consequences.” In another place he remarks, under the head of “Symptomatic Erysipelas:”—“I have seen the most dangerous symptoms

* Ibid. loc. cit. p. 31a.

† Ibidem.

‡ Principles of Surgery, by John Pearson.

immediately supervene to the loss of a very small quantity of blood." (p. 200.)

Turn we now to another* master-builder in the science of disease:—"There are many constitutions which have a tendency to specific diseases that, when injured by fever or any constitutional complaint, readily produce the specific inflammation in such parts of the body as have the greatest susceptibility for any specific action; or, if such parts are affected by any local violence, the parts affected will not go through the *healthy* adhesive inflammation, nor will they enter into the *healthy* suppurative inflammation, but will fall into the specific inflammation peculiar to the habit." Such is the case with an *erysipelatosus* habit." Dr. Mason Good proceeds, in the next place, to associate this "erysipelatosus habit" with an essentially feeble state of sanguification: thus—"In almost every instance there is evidently a diminished vascular action; and hence we meet with the disease far more frequently in persons of delicate habits, women, children, and those who have long resided in warm climates. In one instance it has occurred to me in a strong hearty man, of plethoric form and sanguineous temperament, well known to the world as a public character; but in this case the diet had, from the patient's boyhood, been exclusively that of vegetables." (p. 368.)

Dr. Mason Good would appear to have considered this case as so much the exception to a general rule as to have been under the necessity of offering a special explanation of its occurrence. He presently after remarks—"It has occasionally happened that, instead of diminished vascular action, there has been such a degree of *entony* and caumatic fever as to call for free venesection from the first."

With such views of the essential nature of this inflammation, it will be needless to say more than that Dr. Good condemns depletion altogether in the treatment of the same, save in the rare *exceptional* cases which occasionally present themselves to notice. "Venesection was formerly recommended as a part of the ordinary plan, and has been so of late by a few writers; yet this is to act without discrimination, and to mistake the exception for the general

rule." "I can conceive very few ordinary cases in which the lancet has a chance of being serviceable; while the application of leeches always exasperates the efflorescences." "The bark given largely, as long since warmly and judiciously recommended by Bromfield and Colly, has rarely failed of success."*

In his "Lectures on the Theory and Practice of Surgery," Mr. Abernethy has raised his voice, succinctly but earnestly, in favour of the same views of the nature of erysipelas:—"Erysipelas," he says, "when it comes on spontaneously, or without an evident exciting cause, is indicative of a disordered state of health." "When erysipelas supervenes upon some local irritation, it equally indicates a disordered state of health." And then, "deceiving upon Desault's treatment of the disorder with tartarised antimony, he adds:—"As the disease is connected with weakness, even this medicine should be used with caution." (p. 68-9.)

Dr. Butler's work on "Irritative Fever" is well known to practical surgeons. That physician has recorded a series of cases of erysipelas (for they were instances of that disease under a different signification) which cannot fail to carry great weight with it in relation to the propriety of bleeding under such condition of the system. In summing up the evidence afforded by the materials of his work, Dr. Butler makes the following remarkable statement, which I think particularly worthy of attention in this place:—

* Mason Good, loc. cit., p. 369. The present is not an inappropriate place for introducing the late Mr. Samuel Cooper as an observer tinged with a very decided bias in favour of the views and practice of Mr. Lawrence in this inflammation,—though not prepared, perhaps, to go to the full extent of that surgeon's precepts. In the notes to his edition of Dr. Mason Good's work, both under the head of Erythema and Erysipelas, Mr. Cooper registers his dissent from that doctrine which regards the disease before us as a modification of common inflammation. "From the foregoing observations," says he, in sequel to Dr. Good's chapter on the subject, "it appears that the author was much under the influence of the doctrine that the fever called by him erysipelas, and all kinds of erysipelatosus, or, as he terms it, erythematic inflammation, are essentially connected with diminished vascular action and debility." "After what has been explained under the head of Erythema, in a previous section of this volume, it is unnecessary to insist upon the fact that the local affection is always of an inflammatory nature,—that, anatomically viewed, it requires antiphlogistic treatment." "But should free and even repeated venesection be omitted when the patient is young, strong, or plethoric." (Vol. ii. p. 104.)

* Study of Medicine, by Mason Good, M.D., vol. ii.

"Experience has shown that, out of twenty patients recorded in this work (thirteen of whom were artificers of the dock-yard) who had been blooded whilst labouring under irritative fever, nineteen died." (p. 249.)

Dr. Butter well remarks:—"A person who considers every unhealthy commotion of the mind or body as inflammatory, and employs his lancet accordingly, must be sometimes disappointed in affording the relief which he expected and intended, especially when the mischief arises from an excitement of the nervous system." (p. 242.)

Dr. Fordyce opposed a depletory line of practice in erysipelas with much earnestness:—"Bleeding, and other evacuations (he says), I have always found hurtful. Peruvian bark is the most powerful remedy: it should be exhibited in substance, and in as great a quantity as the stomach will bear."*

Dr. Wells, always an authority on this subject, concurred entirely in the practice laid down by Fordyce for erysipelas.

Mr. Bromfield informs us of the generally fatal tendency of the antiphlogistic treatment during its epidemic continuance for two years in London, while cordials had an opposite influence upon its course.

Heberden, the truthful delineator of Nature, after remarking that erysipelas is "much more common in those who have begun to find their health a little impaired," observes that "this distemper seems to partake of the nature of those which are called malignant more than of the inflammatory; by which I mean that in general it does not require nor bear much evacuation. I have seen very dangerous symptoms follow not only bleeding, but even a gentle purge, though given after the patient had begun to recover."†

Willan describes four forms of erysipelas—E. phlegmonodes, E. cedematosus, E. gangrenosus, and E. erraticum. "This practice (blood-letting) must evidently be improper in the three forms of erysipelas last described; and even in the Erysipelas phlegmonodes it does not always appear necessary. When the blood drawn is sisy, practitioners are often induced to bleed a second

time; but we generally find, in London, that repeated blood-letting aggravates the symptoms, and protracts the disease."‡

Sir Astley Cooper's† views of the speciality of this form of inflammation are well known in this country. "There is something peculiar," he says, "in this inflammation; and, as it is much disposed to produce gangrene, I will here introduce this subject to your attention." And, again, he presently repeats—"It is very common for erysipelatous inflammation to terminate in gangrene." In another place he remarks—"Whatever renders the body irritable‡ predisposes to erysipelas." After recommending the treatment to be conducted with Quinine, preceded by a little calomel at the outset, Sir Astley makes the following statement:—"My colleague Dr. Marcet, now deceased, but late a physician of Guy's, endeavoured to ascertain whether the antiphlogistic or tonic mode of treatment was best for this disease; therefore he put two persons in adjoining beds, having erysipelas, to one of whom, after purging him, were given tonics and a generous diet,—to the other, saline medicines and low diet; blood likewise was abstracted from the latter: they both recovered,—the former rapidly, while the latter remained in a debilitated state for a very considerable period."§

[To be continued.]

EMPLOYMENT OF HYDRO-FERRO-CYANURET OF POTASSIUM AND UREA AS A SUBSTITUTE FOR QUININE.

M. LEMAITRE, interne at the Hôpital la Charité, has made experiments with the above salt in five cases; in two it was successfully used, in three unsuccessfully. —*Journal de Chimie Médicale*, 1850. x

* On Cutaneous Diseases, vol. i. p. 517. Willan's erudite chapter on Erysipelas is an admirable exposition of even the present state of our knowledge in relation to the disease.

† Lectures on the Principles and Practice of Surgery, &c., vol. i. p. 224, et seq.—Sir Astley's account of the disease is very meagre, and much below the requirements of the present day.

‡ Under the head of "Irritable Inflammation" Sir Astley had previously observed—"In this disorder the blood-vessels are much less affected than the nerves."—Lectures on Surgery, vol. i. p. 53.

§ P. 247-s.—Mr. Tyrrell has appended to the text an interesting account of a formidable case of the disease, extending from the right foot to the occiput, which was treated daily (and successfully in the end) with "beef-steaks, three pints of porter, four ounces of sherry, and quinine."

CONSIDERATIONS ON THE CLIMATE OF ITALY,

WITH REFERENCE TO THE TREATMENT OF CHRONIC DISEASE.

By JAMES EDWARD POLLOCK, M.D.,
Licentiate of the College of Physicians, and Medical Resident at Rome from 1842 to 1849.

NO. II.

THE general characters of the Italian climate, of which we propose giving only a sketch, are, for our purpose, to be considered comparatively to those of England.

The shortness of the winter—the absence of high winds—the mildness of the spring—are the three characters which, much more than high temperature, form the peculiarities of Italy between October and May. We shall notice its summer again. Those who expect in that country a uniform high temperature during the period indicated, will, on experience, be much disappointed: hundreds are so annually. Yet high temperature is not the ingredient of most importance in a residence for the consumptive. Evenness of temperature, and shelter from or the absence of high winds, are what prove to be the two sources of comfort to the invalid.

For medical purposes, the climate of Italy may be divided into the stimulant, or bracing, and the sedative; and without entering into details, for which we refer the reader to the many published tables of temperature, &c., to which these remarks can only be considered as supplemental, the former, or stimulant, will be found to embrace Nice, Florence, and Naples—the latter, Rome and Pisa: a sketch of each will suffice.

The stimulant air is felt to be so on every inspiration: it is dry and bracing, without being keen, unless when high winds prevail, which is not unfrequently the case; but its ordinary characters of purity, dryness, as well as the elasticity which it imparts to the muscular powers, and (shall we say) to the tissues, in accordance with our ideas of the word "bracing," render the French epithet, *cif*, peculiarly applicable. Under such influences, the languid in habit are roused, appetite increases, and the digestive powers are strengthened; the

respiratory acts are performed with more vigour, and the elastic structures of the air tubes rendered more contractile; secretion is lessened from the mucous surfaces, and from their great type, the skin. Such sensations we have all felt on some day of blue skies, on the mountain-side, in England, or, it may be, many of us in the upper valleys of the Alps. The excess of this kind of climate cannot be too well remembered—high winds, drying every pore, a hot sun. The effects on the respiratory apparatus in the sanguineous invalid are, lessened secretion, leading to congestions and hæmoptysis; the cough rendered dry and hard; expectoration diminished in quantity, tenacious, difficult. The skin, paralysed, as it were, in its action, throws a double duty on the exhalant powers of the kidneys and lungs, and all the internal organs are congested. The extreme degree of these results is often wondered at by the English medical traveller in the form of acute inflammations running to a fatal termination in 30 or 40 hours.

The inhabitants of the parts of Italy and France in which this form of climate prevails have temperaments formed under its influence, and physical and moral dispositions in wonderful accordance with it. Provence, of which Nice may be considered as an extension, Genoa, Florence, and Naples, produce the sanguineous temperament as if from a hot-house. Irascible and fiery in passions, premature and sparkling in intellect, with too much rapidity for energy, and too little durability for sustained action, they are prompt to feel and hasty to do, and their powers found expended in a premature and unavoidable enthusiasm.* Such is their moral

* We need scarcely remind the reader how the events of the last two years, illumining and then darkening over the horizon of that land endowed with the "fatal gift of beauty," bear out the above remarks. Had Italy been less violent and enthusiastic in her newly-recovered strength, she might now have been free. Who shall say that the more phlegmatic, yet not less energetic northerners would have lost such splendid chances?—or who shall prophesy a bright future to a people endowed with such effervescent energies? In pursuance of this subject, contrast the uniform historical conduct of the north with the south of France. A line drawn from Lyons to Nantes would leave below it the field of the most fearful tragedies of the Revolution. It is true that the south has given birth to great leaders,—as Bearn to Henri IV. and Corsica to Napoleon, but the qualities best suited to the chief are those least available for enduring

picture; the physical corresponds closely. In no European countries are inflammations so rapid or so fatal. It is common to hear of pneumonia, peritonitis, or pleuritis, cutting off a previously healthy man in 40 hours; and diseases viewed by us as chronic become fearfully accelerated with them. Experience has proved that, although the cases are few, in no country is phthisis so rapidly fatal. The great majority of their consumptive cases are "galloping;" active hæmoptysis, rapid softening, hectic of an insupportable violence, and death often in six months or three months, form their usual history. How very many English patients have died at Nice, Montpellier, and other places along or near the northern Mediterranean coast, every traveller can attest. We have several times known such irritation "lighted up" (no inappropriate expression) in cases of quiescent tubercle which had been conveyed to Nice for change of air, that high fever, hæmoptysis, and rapid passage from the first to the second stage of phthisis, have carried off the patient in a few weeks from his arrival; or, if a timely departure has saved the immediate fatal result, an advance from a passive to an active stage, to oppose which is the object of all treatment in consumption, has already taken place. We shall not stop here to point out the practical deductions to be drawn from an observation of these facts, nor indicate the class of cases which are most or least likely to profit by exposure to the stimulant air, but desire to place side by side with the above an outline sketch of the sedative air, such as prevails at Rome or Pisa, and of which the former place affords undoubtedly the best specimen in Europe.

For about fifteen days out of twenty, a calm and mild, yet pure atmosphere pervades the city of Rome, and the whole of the immense plain which, for a distance varying from 12 to 40 miles, surrounds it. The air is (to use the often repeated expression of the invalid) "easily breathed." Its effects on the respiratory system are to allay irritation and to relax the muscular and elastic tissues, amongst which we must class the bronchial apparatus. Secretion is more easy, and becomes profuse in many cases. The mucous surface performing its exhalant office freely, those sensations of tightness, difficulty

of breathing and of expectorating, which in most instances may, perhaps, be attributed to congestions of the minute tubes, scarcely trouble the patient; and we are called on much less frequently than at home to minister to those accidental accompaniments of consumption, which try our ingenuity and tax our patience in so many instances of the disease occurring in our own climate. A lessened cough, freer secretion; and consequently less frequent occurrence of congestions, and the absence of pain, which is so often caused by these or slight pleuritic attacks, may, perhaps, be stated to be the most observable effects of the sedative air on the respiratory function itself. The prevalent wind is from the south-west,—the "Scirocco,"—bearing on its wings often, if not always, evidence of its passage across the sandy plains of Africa, and, nearer at hand, of the malarious district which lies to the south and west of the city. It is hot, and, perhaps, more frequently dry than moist, but occasionally so wet as to render streets, and even staircases, slippery and damp. Under the influence of this air appetite ceases, the tissues are relaxed, the spirit flags, and energy of a sustained character is felt to be a difficulty; a sense of lassitude and weight in the head is almost universal; and those familiar with the crowded receptions of the Roman season have often, on an evening when the gayest have met the gay, seen the influence of the state of the sky overcast even the votaries of pleasure within the walls of some stately palace.

The energies of the people whose home is under such a sky are of a low order. Enterprise has vanished from the city of the Cæsars; and often have we heard foreigners of keen observation, on viewing the ruins of the great that were, and witnessing the sleepiness which prevails for ten months out of twelve over all the activities of the present inhabitants, wonder how ancient Romans accomplished such vast undertakings as her walls, her tombs, her theatres, her very sewers, now evidence to have been done in the former Capital of the World. To this we could find an answer; were this the page for such a discussion, in the fact that the districts now malarious were then cultivated, and that the monuments of the capital were often the result of the labours of captives from every clime.

whilst the heads which directed the enterprises were but rarely indigenous to the Roman soil, and even when so, had a field of climate extending from the snows of Britain and Germany to the luxurious lands of the East, in which to exercise the intellect and train the body to hardihood by military operations. The modern Roman is phlegmatic, slow in action, but ungovernable when temporarily excited, after which he again becomes sullen. On inquiry we found that most of the greatest crimes were committed on momentary impulse, and that murders were by far more frequent during the dead heats of the Scirocco in summer than at any other time.

The morbid effects of such a climate are seen principally on the nervous system. Head affections, phrenitis, and apoplexy, are very common, and often rapidly fatal,—so much so, indeed, that a Commission was expressly appointed by government to investigate the causes of their frequency, who reported that it was due to the influence of malaria. Headache is prevalent to a degree which interferes with the comfort of almost every stranger who visits the city, as well as of those who reside in it. It is generally frontal, and its character is that of weight, or of a tight band causing compression. In many instances we have known it to cease suddenly on a change of wind occurring from south to north. It is not generally intermittent, and is not curable by antiperiodics.

The digestive powers become gradually weakened by a residence in Rome, and dyspepsia of a congestive form prevails to a remarkable extent. Appetite fails, the bowels become torpid, as if their muscular tone was impaired, and purgatives, which have previously been found sufficiently active, cease to have anything like the same effect. This state of things is so universal, that the writer could not recollect a single instance in which it did not occur in all those who spent any time in Rome. Derangement of the biliary function, the result, probably, of slight congestion of the liver, is attributed by many physicians to the influence of malaria; and some, whose long residence abroad entitles their opinion to great respect, are decidedly of opinion that such an effect is very frequent, even when no intermittent affection points to the marsh poison more distinctly. That the kidneys

should also suffer, probably in consequence of the disorder of the secondary assimilating processes, is not to be wondered at. High authorities in this country have already noticed the influence of residence in a malarious district in giving rise to oxalic acid, and probably to other abnormal products, in the urine; and the writer can corroborate all these statements from experience.

It follows from this view that we must regard the southern climate, and especially that portion of it most suitable to the numerous class of chest affections which derive benefit from sedative air, as prejudicial to the nutritive process, the stomach itself losing tone, as evidenced by the loss of appetite, and the secondary processes of digestion and assimilation suffering more or less. This is a very important consideration in the treatment of chronic disease. We have already dwelt on the fact which should never be forgotten, that on the integrity of the nutritive function depends most, if not all, of the reparative efforts of nature which it is our province to assist.

In pursuance of our object, we would now briefly consider some of the more prominent varieties or modifications of phthisis (a disease which constitutes nine-tenths of the cases exported), with a view to arriving at conclusions warranted by physiological considerations as to the advisability of removing them from England to Italy.

Without entering into subtle pathological discussions, it may be assumed that the result of accumulated careful observations leads us to believe that the deposit of tubercle in any organ is the result of a perverted or lowered state of nutrition giving rise to a new formation of low vitality, and that the effects of such deposit, as seen in the subsequent symptoms, arise from two causes—*first*, from a continuance of the same deprivation of the nutritive function which produced the morbid formation; and, *secondly*, from the irritation caused in the tissue of the organ, the seat of the deposit, by which inflammation of an unhealthy character is produced—an effect which varies in intensity according to the greater or less importance of the seat of the affection in the vital scale, as also from the capacity of the individual, from idiosyncrasy or temperament, to produce and sustain an irritative inflammation. We have thus

a disease of *debility* which could not have been produced had the nutritive function existed in integrity; but the results belong to the class of *irritation*, and occasionally exhibit varying degrees of inflammation. Let us consider for a moment the effects of the different temperaments on this state of things. An individual already depressed in vital powers to a degree which has given rise to morbid instead of healthy formations from the blood, undergoes a deposit of extraneous matter in the lung. Should his powers of circulation and muscular tone be low, the blood itself deficient in red particles, the lymphatic system liable to congestions or failures in the elaboration of healthy products, the reaction against the morbid deposit may be trifling, and he may sink, overcome as it were by the first invasion of tubercle, which is generally found extensively deposited throughout a large extent of both lungs, as well as in other organs. Such cases we have observed among the very young, and have witnessed the gradual obliteration of the lung, as evidenced by progressive dulness on percussion, &c., ending in a fatal result without either cough or expectoration having ever been present, a post-mortem examination revealing a dense mass of tubercle in its first stage. But to this class also belong the slower scrofulous cases where violent irritation is absent, frequent external attacks on the glandular system often alternating (as it were) with the progress of the affection in the lung, and even alleviating the symptoms of the latter. But if the sanguineous temperament prevail, indicating a proneness to inflammatory action, an irritative excitement is at once set up, the parts surrounding the deposit are injected with blood, and hæmoptysis of an active character is generally among the earliest symptoms of the lesion. The history of such a case will generally be found to be that of a rapid destruction of the tissue of the lung, the tubercle undergoing its changes with dreadful speed; while daily chills, followed by burning heats and profuse sweats, with a rapid pulse, rarely under 100, indicate the sympathy of the whole system with the morbid local actions. Hæmoptysis is frequent, the cough is hard, the breathing tight and difficult, the expectoration frothy, showing how much the bronchial membrane is irritated; while slight pleuritic attacks are more fre-

quent in this than in any other class of phthisical patients. Observation shows that such cases are by no means inconsistent with the scrofulous diathesis to which we generally attribute a power of producing only slow inflammatory action. On the contrary, should the sanguineous temperament be superadded to an hereditary tendency to scrofula, and such an individual be attacked with tubercle, this combination may be said to present the most rapid form of phthisis. The tendency to bilious derangement in persons possessing the sanguineous temperament is a serious consideration in balancing the chances for and against the prolongation of life. The supply of healthy blood furnished from the digestive process, if interfered with by frequent, even although slight, failures in the elaboration of healthy chyme from the food, soon becomes insufficient to support the enormous drains from the system by expectoration and sweats alone, and the emaciation is rapid. From our observations on the climates of France and Italy, it will be seen that the stimulant air of Provence, Nice, or Naples, would eminently disagree with such cases, from the tendency of the latter to produce overaction of the vascular system. The sedative air of Pisa or Rome is often productive of excellent effects on the circulation, the pulse becoming calmer, and on the respiratory organs, as irritation is decidedly lessened by its mildness, cough and various uneasy sensations being allayed. But this improvement is only palliative, as, if the primary curative indication be neglected, that of furnishing by an improved state of digestion and assimilation a more healthy blood by which the reparative process is furnished with vital material, we cannot hope to withstand effectually the ravages of the disease.

There can exist but little doubt on the minds of impartial observers that the very properties on which depend the sedative effects of certain climates on the respiratory functions, are directly prejudicial to the full and healthy exercise of the digestive, and, in connection with the sanguineous temperament, which we have found to be that chiefly open to such influences, we shall here notice this important subject a little more in detail.

The European localities which have climates possessing this so-called seda-

tive property are generally marshy, or in such neighbourhood of marshes (or that peculiar soil which produces malaria, and which by no means needs stagnant pools for its development), that diseases of an intermittent form are known to prevail extensively at some, or all seasons of the year. The city of Rome, and the country around it, are well known to be affected with such affections in the autumn; and during the period we passed there, no winter was free from cases of tertian and various other periodical affections. The malarious atmosphere thus prevails at all seasons, although it follows there the usual rule of attaining its greatest intensity in autumn. There is, it is true, no marsh within forty miles of Rome, at which distance the Pontine malaria may be said to lie; but the soil is of a porous volcanic structure, and the heavy rains of the winter and spring, sinking through the superficial stratum, are afterwards drawn upwards through a thick, wild, vegetation, and thus give rise to the poisonous exhalations to which we are accustomed to attribute intermittent affections. Pisa, which is placed at a few miles distance from the mouth of the Arno, has all the intervening land between it and the sea in a positively marshy state. The almost incredible fact, that the city which now stands at least three miles from the mouth of the river was formerly on the "embouchure" itself, is sufficiently attested by historical and existing local evidences of its naval importance as a port, and proves the alluvial nature of the soil, which the river has thrown up between its present site and the Mediterranean.

Without entering on the discussion as to the influence of malaria in checking and curing consumption directly by exercising a counter-influence on the system,—the two states being supposed to be, as it were, incompatible,—we would call attention to the fact that the Italian climate, and perhaps the others which prove most beneficial or palliative in phthisis, are *decidedly malarious*. It is also undoubtedly true, that the two diseases do not often coexist in those localities; no instance of the double affection has ever occurred under our notice during a residence of seven years, while we have seen many of the healthy English community attacked by some form of ague. The fact of hectic fever

being itself distinctly an intermittent affection, and so preoccupying the system, may tell in two ways,—in favour of theorists who hold the indemnity to be due to the incompatibility of the two affections, the one filling up the system to the exclusion of the other, and against them—since it is a well-established observation, that the occurrence of any form of intermittent renders the recipient of the poison more obnoxious to malarious influences than he was before. Leaving the theory to the ingenious, we are satisfied that malarious airs are generally felt by the phthisical to be light, easily breathed, and unirritating. It will be remembered that at Rome and Pisa the air from the marshy districts is *southerly* and in this point *per se*, which implies the absence of northerly and easterly winds, we can see a reason why chest affections with symptoms of irritation should derive advantages from a residence in these cities of the plain. There remains, however, a very important consideration,—that the malarious influence, while it is sedative to the respiratory, is prejudicial to the digestive functions. The failure of appetite, the constipation and resulting languor, and often recurring attacks of bilious derangement, are a *serious set-off* to the advantages which the chest affection derives; and we would call the very active attention of the profession to this point in considering the advisability of exporting patients of the bilious temperament to Italy for any lengthened residence.

[To be continued.]

UNIVERSITY COLLEGE, LONDON.

At the session of the Council on Saturday last the Fellows' Clinical Medals for the best observations on cases at the hospital were awarded as follows:—The Gold Medal for the Winter Term 1849-50, to Mr. Edward Jackson, of Sheffield; the Gold Medal for the Summer Term 1850, to Mr. Thomas George Fitz Gerald; and a Silver Medal for the same Term to Mr. Robert Bowman. The Andrews' Scholarships were fixed as follows:—For competition in October next, a Scholarship of £100, and two of £50 each; for competition in October, 1852, one of £70, and two of £45 each.

CASE OF
**RAMOLLISSEMENT OF THE CEREBELLUM, TOGETHER WITH
 THAT OF THE CEREBRUM;**

WITH FATTY DEGENERATION OF THE
 HEART, AND TUBERCULAR ABSCESSSES
 IN BOTH LUNGS.

BY JOHN DAY BROWN, M.D.
 Strood, Kent.

(Communicated by F. J. BROWN, M.D.)

THIS case is reported because of the small number of instances in which softening of the cerebellum has been observed.

E. K——, æt. 39, married, and the mother of several children, suffered, during the last five years of her life, with occasional attacks of giddiness, pain in the head, and sickness, which were accompanied by numbness in one of the lower extremities. She was bled from the arm, or cupped at the nape of the neck, whenever these attacks occurred. During the months of December, 1849, and of January, 1850, she laboured under symptoms of chronic inflammation of the brain, which closely resembled those observed in idiopathic fever attended by an unusual degree of brain affection. She had scarcely recovered from a miscarriage when these symptoms appeared: her power of memory became impaired; paralysis of the left lower extremity ensued, with weakness of the right leg; and rigidity of the muscles of the lower limbs was occasionally, not permanently present. Emaciation progressed, and, at the period of her death, was considerable. She had an attack of bronchitis on the 7th June, from which she recovered.

On the 19th she was affected by paroxysms of breathlessness, which recurred five or six times during three consecutive days. There was now a rapid loss of strength, and a still further impairment of memory, and the patient died in a paroxysm of breathlessness on the 29th June, 1850, at 4 P.M.

Throughout the day and the preceding night she fancied that she saw deceased persons. Her consciousness never at any time failed her, although

she had a dull, vacant aspect of countenance. She stated, in answer to inquiries, that there was a sensation of "squashing" in the back part of her head; and that, whenever she was in an upright posture, her feelings were as if she must pitch forward.

An examination of the body was made 42 hours after death. The skull was dense, and greatly thickened, particularly anteriorly and laterally. There were about three ounces of serum effused beneath the membranes; the ventricles contained but little fluid; the vessels of the pia mater were dilated; no disease was found in the arteries at the base of the brain; the cerebral convolutions were healthy and moderately firm; there was white softening of the corpus callosum, so that its superior surface tore into the form of an ulcer by the stretch occasioned to it by slicing the convolutions. The fornix and its crura were almost destroyed, and the peduncles of the pineal gland were completely removed by the process of ramollissement; the crura cerebri were in a state of softening in the vicinity of the pons varolii; the superior vermiciform process, and the upper surface of the hemispheres of the cerebellum, were in a state of softening, being ragged and diffuent. The substance of the medulla oblongata was sound.

The heart was affected to an extreme degree by fatty degeneration: it presented the appearance of a gelatinous sac, with a few red fibres in the left ventricular parietes. Coagula were found at the apex of the left ventricle, but none in the ventricle on the right side of the heart.

There were old pleuritic adhesions; the lungs were emphysematous anteriorly, and on section presented numerous tubercular abscesses, some of them of considerable size: these cavities contained thin pus, and had no communication with bronchi.

The liver was enlarged and fatty.

The spleen was actually liquid within its capsule, so great was the softening.

The kidneys were greatly softened, and flakes of cortical substance were peeled off with the capsule.

The intestines and mesenteric glands presented no diseased appearance.

MEDICAL GAZETTE.

FRIDAY, DECEMBER 13, 1850.

THE recently published Report of the Commissioners of Lunacy contains some facts of interest in a medical point of view.* In addition to a statistical summary of the number of lunatics, male and female, confined in the various hospitals, asylums, and licensed houses throughout the country, there are tables showing the circumstances connected with the outbreak of, and mortality caused by, the malignant cholera in those establishments. We shall at present direct our attention to the general statistics of the insane. It appears from this document, that the total number of lunatics falling under the cognizance of the Commissioners, exclusive of single patients under the care of medical gentlemen and others, amounts to 15,079, thus distributed —

Private patients	3,774
Pauper patients	11,305

Total	15,079
-------	--------

Arranged according to sex, the numbers stand thus :—

	Males.	Females.
Private	1,906	1,868
Pauper	5,168	6,137
	7,074	8,005

It will be perceived that the female are about one eighth more numerous than the male lunatics; and this preponderance is chiefly manifested in the Pauper class.

It appears that about one half of these lunatics are confined in asylums, the other half being distributed in hospitals and licensed houses :—

Asylums	7,140
Hospitals	1,208
Metropolitan Licensed Houses .	2,945
Provincial Licensed Houses .	3,786

* Copy of the Report of the Commissioners of Lunacy, to the Lord Chancellor. Printed by order of the House of Commons: 1850.

It would thus appear that a very large proportion of lunatics, amounting to nearly one-fifth of the whole, are congregated within the walls of the Metropolitan Licensed Houses, and that this number falls only a little below that assigned to the whole of the Licensed houses throughout the Provinces.

As we are in the last year of the decennial census, it is impossible to calculate with accuracy the proportion which the number of lunatics bears to the entire population of England and Wales. Judging, however, from the progressive increase of population, it may be fairly assumed, from the numbers given in the return, that insanity is not on the increase, as some have asserted, but that the cases now bear a smaller proportion to the population than they did at the last census. Its great prevalence among pauper females, as shown by this Report, is worthy of note, as an index of the distress and misery which afflict this class of the population.

The remarks appended to the Return tend to show that the Commissioners have exerted themselves to enforce the provisions of the law for the protection of these unfortunate beings, and they have not hesitated to expose delinquencies, where they have been brought to light. They say :—

“We have now the satisfaction of reporting that the various Institutions for the insane throughout the country are in an improved state, and that the conduct of the Superintendents, Officers, and Attendants, in reference to the treatment of patients and the management of Lunatic Establishments, is for the most part humane and judicious.

In several instances, however, the visiting Commissioners and Justices found it necessary to animadvert upon the excessive use of mechanical restraint; on the neglect of cleanliness; on inadequate ventilation; on want of sufficient attendants; on improper or deficient diet; on the dirty condition or scanty supply of bedding and clothing.

on irregularities in the medical books; and on other defects. And in about seventy instances these defects were deemed of sufficient importance to require the special interference of this Board, by whose direction letters were addressed to the parties inculpated, the effect of which has been that the defects thus noticed have been wholly or partially remedied."

In some few instances the defects of management were so glaring that the Commissioners have felt it necessary to enter into some details respecting them. Three licensed houses were especially noticed, in which it appears the Visiting Commissioners discovered that it had been the practice to place clean sheets on certain beds during the day, and to remove them at night, thus giving a fictitious appearance of comfort to the patients' beds. In one of these establishments the neglect of the patients was so gross that the Commissioners recommended the withdrawal of the license. In reference to metropolitan asylums and hospitals, the Commissioners observe:—

"In our last Annual Report we took leave to call attention to the burial-ground adjoining one of the airing-yards of St. Luke's Hospital, and expressed a hope that the Bishop of London would eventually interfere in the matter. We have now the satisfaction of stating that his lordship did interfere in the most prompt and decided manner; and that, in consequence thereof, this objectionable burying-ground (which contains only 1,000 square yards, and in which 200 bodies, on an average, were annually deposited) was closed in the month of August last."

Guy's is, we believe, the only London hospital for the general reception of patients to which lunatic wards are attached; and, with respect to these, the following observations occur in the report:—

"In the Annual Report, dated 30th June, 1848, we had occasion to notice the defective condition of the wards appropriated for the reception of insane

females in Guy's Hospital. Special reference was at that time made to the want of baths, the offensive atmosphere in the rooms, the insecure state of the window-fastenings, and also to the fact that three female patients were found by the Commissioners, at the time of their visit, in a state of perfect nudity, lying in the loose straw which constituted their bedding.

"It is satisfactory to report that, in all the particulars referred to, considerable amendment has taken place. Suitable baths have been fitted up, and bedding of a superior description has been lately provided. We have also to observe that a material improvement in the condition of this ward, and the treatment of the patients, is manifest. The amount of mechanical restraint to which they were formerly subjected is now greatly diminished, and efforts are made to increase their comfort, and to induce them to engage in suitable occupations.

"We are informed that an additional day-room is about to be appropriated to the use of the patients. This addition will afford a better means of separating and associating the inmates, and will tend materially to improve their condition and promote tranquillity.

"Notwithstanding these various additions and improvements, it is our duty to add that the ward appropriated to the insane in Guy's Hospital must, in our opinion, *owing to its situation*, continue to be very defective in several important requirements, and fail to afford the inmates many of the advantages which are calculated to alleviate disorders of the mind."

It appears further, from the Report, that the number of female lunatics now confined in these wards amounts to 22. From the remarks made, it is to be inferred that the Commissioners object to the locality of this Hospital-asylum, and they throw out a suggestion that its removal to another spot would be attended with benefit to the lunatics. There may be some reason in this suggestion; but the terms of the will of the founder, confirmed as they have been by an act of Incorporation, do not permit such a change, except by the intervention of the Legislature.

The newly-established *Asylum for Idiots* is thus favourably spoken of:—

"In continuation of our last Report relative to the provision made for the care and training of idiots as a separate class of insane, we have the satisfaction of stating that the comforts and advantages of the benevolent institution, Park House, Highgate, and the benefits conferred thereby upon the unfortunate class for whom it is designed, have been justly appreciated by the friends of the patients (who are more properly termed pupils) and by the public. This Board have received from two of their number who recently visited the Asylum a detailed report, showing that considerable progress has been made in carrying out the objects and maturing the plans of the institution. It appeared, at the same time, to the Visiting Commissioners that the system admitted of further development and improvement, and they made several practical suggestions with that view. A copy of their Report has been transmitted, by order of this Board, to the Committee of the Asylum, who, the Commissioners feel assured, will give every attention to their suggestions.

"It only remains to state that the accommodation afforded by the present premises at Highgate having proved inadequate to meet the increased and increasing numbers of applications for admission, it has been determined to extend the buildings: in the meantime, advantage has been taken of a very eligible offer of suitable premises at Essex Hall, near Colchester, to form a branch establishment in connection with that at Highgate—a temporary arrangement which received our concurrence; and we have felt justified in considering and treating the two establishments as one institution."

It is a remarkable fact that the cases of *suicide* have not exceeded eight during the last year, and the Commissioners justly observe:—

"Considering that the total number of lunatics in asylums in the country is not less than 15,000, and that the ancient system of mechanical restraint has in many institutions been altogether abandoned, and in most others exceedingly diminished, we cannot but consider that the number of deaths by suicide is

smaller than might have been anticipated, and that the fact is highly creditable to the superintendents, medical officers, and assistants, of the various establishments for the insane, to whose vigilance and care this result must be mainly attributed. Of the suicides referred to, six—viz., three males and three females—were by strangulation, one male by cutting his throat, and a female by drowning. In the last-mentioned case, which occurred in the metropolitan district, the lady referred to escaped from her attendant while walking with her in the country, secreted, and afterwards drowned herself."

In conclusion, the Commissioners advert to the unprotected state of the property of lunatics of the middle classes:—

"The important subject of the protection and administration of the property and income of lunatics under certificates has continued to occupy much of our attention, and we have had frequent occasion to regret the very defective state of the existing law, more especially as respects the property of patients, tradesmen, and others, of small means, or whose mental malady is likely to be only temporary. We earnestly hope that this subject will receive your Lordship's early consideration."

Anything more unjust than the law of England in this respect, it would be impossible to conceive. The cost of a commission in its cheapest form in an undisputed case is not less than three hundred pounds; and where the property is of sufficient magnitude, the costs are easily made, by process of law, to expand in a direct proportion to the estate of the lunatic. Thus the expenses of commissions among the higher classes are rarely under one thousand, and sometimes reach to five thousand pounds! The charge made by the Court of Chancery on the relatives of a tradesman for placing his property under their safe custody, and preventing waste, as we are informed, is at the lowest amount *three hundred pounds**, although

* In Elmer's "*Practice in Lunacy*" the cost of finding whether a man be lunatic or not is set

his lunacy and incompetency may be so palpable that a common jury of twelve of his neighbours would settle the question in five minutes. The result of this infamous system of extortion is, that, comparatively speaking, few commissions are taken out. The relatives prefer incurring any risk rather than seek the so-called *protection* of the Court of Chancery. In fact, it is only where property belonging to the lunatic is worth the risk, trouble, anxiety, and expense, which inevitably attend Chancery proceedings in lunacy, that an inquisition is sought for. In the meantime, dishonest persons may refuse to pay debts to a lunatic's estate. The dividends on investments in Government Funds or other securities, rents of estates and house property, and funds at bankers, are withheld; for no one can give a legal receipt except under an order of the Court of Chancery. This renders an inquiry necessary, with the payment of extortionate fees, for the support of an antiquated system of injustice.

The working of such a system is clearly shown by this Report. If we leave out the pauper class of lunatics altogether, and set down the numbers confined during the past year at 3774, there were only 238 cases in which inquisitions were held—i. e. among *eleven* persons above the pauper class there is only *one* who has been found lunatic by inquisition! In many of these cases a charge of three hundred pounds, or even one half of this sum, for answering a very simple question, is doubtless so disproportionate to the means of the lunatics that it cannot be incurred. We do not see why a simply constituted Court, with one competent Commissioner, should not be allowed to decide these cases cheaply and speedily.

down at £123. 2s. 6d.; but this must be the hypothetical cost. The period which the Court of Chancery is supposed to take in order to decide this question is *six months*; but this must be the hypothetical period.

The relations of a poor lunatic have as great a right to protection as those of a wealthy patient. The creation of a money-test deprives them entirely of this right, and often throws upon them, in addition to vexatious delays, an unnecessarily heavy charge for the support of the lunatic.

Reviews.

Remarks on Insanity: its Nature and Treatment. By HENRY MONRO, M.B., Oxon, Fellow of the Royal College of Physicians. In Two Parts. Part I. Pamphlet. 8vo. pp. 75. London: Churchill. 1850.

THE object of these "Remarks" by Dr. Monro is to prove that insanity is a disease of deficient nervous tone consequent on loss of vitality. The argument is introduced by observations on the classification of the insane. All cases of insanity are ranged by the author under three divisions:—"1. Acute stages of active insanity; 2. Chronic stages of active insanity (both of these stages manifesting varieties of form)—namely, in some, general delusions, in others partial; in some, great excitement, in others great depression; in some, intermitting paroxysms, in others continued; in some, intellectual derangement, in others only moral; and 3. The imbecile stage, or the state of wreck after the storm has passed." This classification the author thinks best adapted to treatment.

Dr. Monro treats at considerable length of the corporeal nature of insanity, and in this part of his work shows its dependence upon a state of depression of the nervous centres, establishing his position from a consideration of the physical condition of the insane. In the second chapter the author proceeds to the question, whether there is anything in the mental phenomena of the insane which could not be accounted for on the results of loss of nervous tone. This inquiry is pursued by a consideration of the most common mental phenomena of the insane, by a comparison of those mental conditions which are very similar to insanity, and by the consideration of

the acknowledged causes of those conditions, as well as of the mode of access of those causes. This portion of Dr. Monro's pamphlet is one of the best expositions of the subject that we have met with, being written in a peculiarly clear style, and presenting a picture faithfully drawn from nature. The conditions approaching to that of insanity are sleep, dreaming, somnambulism, waking trance, voluntary abstractions, transporting passion, the mental state of the infant, the mental state of old age, delirium caused by external agents, delirium occasioned by poisonous matter of internal origin, and, lastly, delirium caused by mechanical pressure.

This part of the work closes with the proofs of the loss of vitality and the causes of this nervous deficiency.

This is an extremely well-written essay, and well deserves the perusal of professional men, whether especially engaged in the treatment of the insane, or occupied in general practice. It is not undeserving the attention also of educated non-professional persons, on account of its intrinsic literary merits. We hope that it will not be long before the second follows this first instalment of so valuable a practical treatise.

Observations on the Treatment of Phthisis Pulmonalis. Pamphlet, 8vo. pp. 23.

Lectures on Clinical Medicine. Parts I. and II. Pamphlet, 8vo. pp. 92. By JOHN HUGHES BENNETT, M.D., F.R.S.E., Professor of the Institutes of Medicine, and of Clinical Medicine, in the University of Edinburgh. Edinburgh: Sutherland. London: Simpkin and Co. 1850.

THESE essays have already appeared in one of our contemporaries: they have received very considerable additions before their publication in a separate form, and will be followed by others of a similar character.

The first essay consists of an excellent practical exposition of the value of judicious hygienic treatment in arresting the course, or preventing the development of phthisis. This pamphlet has two faithfully-executed coloured engravings of specimens of morbid anatomy of phthisis.

The second contains clinical lectures on cases illustrative of the processes of simple, cancerous, and tubercular ex-

cessions, with their pathology and treatment; on pneumonia, cancerous exudation into the liver, cancerous ulceration of the oesophagus, simple stricture of the pylorus, profuse hæmatemesis, aneurism of the aorta, and plithisis.

The third comprises Lectures on the Classification and Diagnosis of Cutaneous Diseases.

Each subject is fully illustrated by cases and woodcuts. These publications being already known to many, and emanating from a pathologist of established reputation, require little more than this announcement of their publication in a separate form.

The Nature and Cure of Consumption and Indigestion, Scrofula, and Nervous Affections. By G. CALVERT HOLLAND, M.D., late Physician to the Sheffield General Infirmary, Bachelier es-letres of the University of Paris, &c. &c. 8vo. pp. 208. London: Orr and Co. 1850.

Cases illustrative of the Cure of Consumption and Indigestion. By G. CALVERT HOLLAND, M.D., &c. &c. Small 8vo. pp. 104. London: Orr and Co. 1850.

We were rather surprised on perusing the first of these two works to find that, according to its author, the medical profession is deplorably ignorant of the influence of the nervous system on the functions of digestion and nutrition, while Dr. Holland alone appears to have discovered that this system has a "widely-pervading influence" on the phenomena of life. He tells his readers that there are few disorders that cannot be brought within the comprehension of the general reader: the comprehensions, however, of the members of the profession to which Dr. Holland belongs are of a different order, and cannot so readily apprehend the phenomena of disease! Such, at least, we gather to be Dr. Holland's opinion. We suppose, however, that we must except the mind of Dr. Quin, the homœopath, to whom Dr. Holland dedicates his book with great laudation. The object of the first of these publications is obviously beyond the pale of the profession, as it is addressed to the public. Let the public, it judges: we shall

tion upon it.
is unto the first, it
he non-profession

eye. It sets forth the virtues of tar-water and cod-liver oil in consumption, and of a combination of hydropathy with medical treatment and dietetic rules in the case of indigestion. *Valent quantum valere potest!*

On Bengal Dysentery and its Statistics; with a Notice of the use of large Ene-mata in that Disease, and of Quinine in Remittent Fever. By JOHN MACPHERSON, M.D. Pamphlet, 8vo. pp. 63. Calcutta. 1850.

FROM 1830 to 1850 there were admitted into the General Hospital, in Calcutta, 2,044 cases of dysentery, of which 457 or 22·3 per cent., died. The average mortality from the disease was, at Bombay, 18·3 per cent., and at Madras, 30 per cent. among civilians, and only 5·3 for the military. Very full tables are given by the author, which justify his conclusions.

The structural changes produced by the disease are also presented in tabular statements. On a comparison of these statistics of *acute* and *chronic* dysentery, it appears that the liver is more frequently disordered in the latter form of disease, in which also it is more generally small and indurated, while in the acute form it is enlarged and soft. The spleen is more frequently enlarged in the chronic disease.

Our brethren in India are among our most industrious cultivators of pathology. The obligations under which they have placed the medical profession by their labours, is further increased by Dr. Macpherson's pamphlet.

The Accommodation of the Eye to Distances. By WILLIAM CLAY WALLACE, M.D. Pamphlet. 8vo. pp. 36. New York, and London: Wiley. 1850.

THE author minutely describes many structures in the eye of man and the lower animals by which the adjustment to distance is effected. We extract, verbatim, the author's description of one apparatus by which this is mainly performed, and to the discovery of the use of which he lays claim:—

"The spherical lens is suspended by a ligament which is formed by the membranes of the vitreous humor, and is sometimes covered with pigmentum nigrum. Beneath the crystalline, there is a muscle (the campanula Halleri) which, though it

varies in shape and size, is very conspicuous in the halibut, the dolphin, and the striped bass. In the halibut the muscle is hatchet-shaped, and proceeds diagonally from the lower pole of the crystalline body to be attached slightly to the uvea, but firmly to the anterior and lateral portions of the membranes of the vitreous humor. When the muscle, which is supplied by a large branch of the third pair of nerves, contracts, the crystalline approaches the cornea; and when it is relaxed, the crystalline is drawn back by the elasticity of the membranes of the vitreous humor, some of which passing through the retina at a line that, in animals furnished with spherical lenses, divides the lower portion of the tunic, are firmly fixed to the choroid.

"The campanula Halleri has by some been described as the ganglion of the crystalline; by others, as a cartilaginous body: but, so far as I can ascertain, its muscular character, its passage through the loop at the back of the iris, its attachments and use, were unknown until 1834, when I pointed them out." (pp. 9-11.)

We may observe that this monograph contains also minute descriptions of other parts in the structure of the eye. We regard it as a very useful contribution to anatomical science.

Proceedings of Societies.

MEDICAL SOCIETY OF LONDON.

Nov. 30, 1850.

DR. J. R. BENNETT, PRESIDENT.

Inhaling Apparatus.

DR. SNOW exhibited and described the method of using some apparatus for the administration of various volatile medicines by inhalation, and in reply to questions as to the dose and temperature to be used, stated that he had come to the conclusion that about half the quantity of material placed in the instrument became absorbed by the patient, whilst the remaining part was expired, and consequently lost; and that such drugs as opium and stramonium required a temperature between 360° and 410°, but that hydrocyanic acid, chlorine, and the like, could be given without artificially heating them.

Cauliflower Excrescence of the Os Uteri.

DR. CORMACK read a paper upon cauliflower excrescence of the os uteri, illustrating the subject by a case from his own practice.

A patient, æt. 30, mother of five children, whose general health was good, had an attack of menorrhagia in September 1847, and was treated with advantage by tannic acid internally. She was pregnant at the time, and there had been, during the first month of her pregnancy, a slight discharge.

All went on well till the 28th of November, when the author was summoned to attend her, she believing herself to be parturient. There had been but little pain, although a great discharge of watery fluid had taken place, which was gradually followed by alarming hæmorrhage. The author, anticipating a placenta prævia, made a digital examination, and discovered a tumor of considerable size affixed to the anterior lip of the uterus, the os itself admitting only the tip of the forefinger. The author injected a strong solution of sulphate of alum, plugged the vagina with compresses soaked with the same, and administered an opium enema by the rectum. By these means the bleeding was arrested, and the patient obtained some repose. At 6 A.M. of the following day the pains became sharp and regular: the tumor had diminished much in bulk; it had shrunk almost to a roughness, and was not tender. After eleven hours, no change having taken place in the meantime beyond the drain of dirty, offensive fluid, the labour pains became more frequent, but not very effectual. At 8 P.M. there was sudden discharge of blood. The author punctured the membranes and exhibited ergot. In an hour a healthy living child was brought forth; a little brandy and tea was given to the patient, and she was left in charge of her attendants with a tolerably good pulse.

On recovery from her confinement, the tumor still remaining of its original size, the author, with the concurrence of Dr. Henry Bennet, proposed removal by the knife, determining to take away also at the same time the portion of the uterus to which it was attached. To this the patient did not consent. Mr. Fergusson's opinion on the matter was taken, and, in accordance with that opinion, no operation was then resorted to.

Matters continuing to become more unpropitious in spite of the employment of local and constitutional astringents, the vagina being excoriated, on the 6th of February, 1848, Mr. Fergusson excised the diseased parts with temporary relief. In two months time fresh excrescences had sprouted forth, the bleedings reappeared, and the accompanying pain required enormous doses of morphia to allay it. On the 17th of July the sufferer died during an attack of hæmorrhage.

The post-mortem examination showed

the vagina to be ulcerated, the uterus to be enlarged and cartilaginous, and having its internal surface covered with mammillations about the size of a pea, whilst no disease existed in the urethra, bladder, or ovaries. The author expressed his opinion that the operation should have been performed at a much earlier date, but that, from the slight pain accompanying the disease at its commencement, the patient would not submit. He drew attention to the styptic powers of gallic acid when given internally, and stated that in weighing the question as to whether the disease could be successfully removed by the knife or ligature, he kept in view the results of Dr. Simpson's experience, which was of a nature favourable to putting in force operation.

Dr. Andrew Anderson's theory as to the nature of cauliflower excrescence the author considered as countenancing surgical interference.

Dr. MURPHY said two points of interest were contained in the paper just read. First, the absence of any inconvenience during pregnancy, the disease appearing to be in abeyance; and, secondly, the mode of treatment: his opinion was averse to operation. In one case of his own the patient died three weeks after the operation; in a second, three months after the operation; whilst a third was carried off by peritonitis. He also remarked upon the result of the pressure upon the tumor.

Dr. HENRY BENNET made some observations in respect of the nature of cauliflower excrescences. He considered it as proved that there were two kinds—one which was vesicular, and another which was distinctly malignant, and had been described by Dr. Clarke under the name of cauliflower excrescence. The former might be successfully removed, whilst the latter was almost sure to return. In his own practice he only met with one case of the vesicular form, which he ligatured without permanent benefit. He had seen three cases of the malignant polypoid variety, one of which he attended with Dr. Murphy. The tumor was removed by ligature: however, the issue was fatal. Nevertheless, he should not hesitate to perform the operation of extirpation, as there were cases on record which were said to have had a happy termination. He stated as fact that cancerous disease of the uterus had never come under his notice in its first stage of development, and that he had never seen a clear case of the disease end otherwise than fatally.

Mr. STILLMAN related the particulars of a case of fatal hæmorrhage from a cauliflower excrescence in a woman, mother of one child. The hæmorrhage took place

suddenly without previous warning, and caused death in a very short time.

Mr. I. B. BROWN considered operation justifiable if there were any chance of prolonging or rendering more comfortable the patient's existence. He begged to call attention to the diminution caused in the tumor by the pressure of the plug introduced into the vagina.

Mr. HUBB expressed a strong opinion against the propriety of operating. He thought the members had been discussing two diseases under the same name. There were clearly two forms of cauliflower excrescence—one malignant, and the other not so.

Mr. P. MARSHALL said he had seen many cases of the disease: he had always found them unmanageable. He related a case of malignant disease which remained in abeyance during pregnancy, but which, after the patient's confinement, speedily terminated her existence. He differed from Dr. Bennett in respect of the recognition of malignant disease of uterus in its early stages. He had more than once traced malignant disease of uterus from its commencement.

December 7.

Dr. SNOW exhibited

An Enlarged Heart,

which measured 15 inches in circumference, $5\frac{1}{2}$ from base to apex, and weighed, after being carefully emptied and washed, one pound four ounces. There was but slight valvular disease. The man from whom it was taken died at the age of 52: was a porter of intemperate habits. The lungs were emphysematous. The kidneys were in a state of granular degeneration. Anasarca and albuminuria had existed for two years.

Mr. HENRY SMITH brought before the Society a specimen of

False Passage in the Urethra, leading to the Bladder just above the Natural Orifice,

and made some observations respecting the complication this state of matters would make in the performance of Mr. Syme's operation for the relief of stricture.

Mr. CANTON spoke of the great value of Avery's urethral speculum in such cases, as with that instrument the surgeon could distinguish the aperture of the stricture into which he was about to pass the sound.

Mr. CHIPPENDALE and Mr. BORLASE CHILDS spoke with great confidence of *their own skill* in passing the catheter, and therefore considered operation unadvisable.

Mr. COX read a paper upon

Laryngismus Stridulus, or Crowing Inspiration of Infants.

The author gave a concise *resumé* of the views held by the most esteemed writers upon the subject. From his own experience, he was led to infer that the disease was more frequent in females than males; that children of strumous habit were peculiarly liable to it; that artificial feeding, by affording only insufficient nourishment, was a predisposing cause; that enlarged thymus was only a very rare cause of the disease.

He considered the analogy between laryngismus stridulus and epilepsy to be very strong.

1st. The symptoms were in some measure similar.

2d. That patients subjects of this disease in infancy sometimes became affected with epilepsy in after-life. He had seen instances of this.

3d. That epileptic seizures were often preceded by laryngeal spasm.

The author considered a retardation of the pulse as premonitory of an attack: he had noticed the pulse fall from 115 to 80 or 85.

In the treatment of the disease he had found chloroform very useful in removing the suffocative spasm: he had never met with any inconvenience from its use: he administered the vapour by placing 20 or 30 drops upon a piece of lint.

General tonic treatment he found the best preventive against the recurrence of attacks, especially in scrofulous children.

Hydrocyanic acid had proved in his hands most efficacious in curing the disease after it had become centric, when an irritability of the spinal cord had been set up.

The author brought forward twelve cases.

In one there was congestion and inflammation of the meninges of the cord, from the foramen magnum to the 5th cervical vertebra, arising from a fall across the back some time previously: in another, aneurism of the arch of the aorta involved the recurrent laryngeal; the child was four years old. In five cases artificial feeding probably had been the predisposing cause.

Dr. SNOW suggested, from the dangerous nature of chloroform when in the hands of the inexperienced, that it should be diluted with alcohol, and left with the friends of the patient, in order that it might be given on the instant of the attack.

Dr. GOLDING BIRD had found colchicum very useful in the treatment of the disease, especially in children of a plethoric habit: he would be afraid to employ chloroform.

Dr. Willehire, Mr. Hind, Dr. Crisp, Mr. Dendy, Dr. F. Winslow, spoke upon different points in the author's paper.

HARVEIAN SOCIETY.

Fatal Case of Carcinoma of the Ileum, from Thickening of its Lower Portion at its junction with the Cæcum, caused by Cephalomatous Deposit underneath the Mucous Membrane, with a large Tumor of the same character imbedded in the Folds of the Omentum, which surrounded and compressed the Caput Coli. By DR. POWELL.

E. M., æt. 60, married, of nervo-lymphatic bilious temperament, formerly lived at Acton, stoutly made, was subject to torpid bowels from her youth, especially since her confinement some twenty years past, which required the daily use of aperient medicine. This became aggravated about six weeks previous to her death, but she was not confined to bed for more than a week previously, from which time she had no evacuation from the bowels. Had been treated by calomel and croton oil, followed by cathartic mixture and injections of turpentine and olive oil, but without effect, all medicine and aliment being rejected, and soon attended with feculent discharge from the stomach. Seen by me three days previous to her death. I found her much reduced, with constant vomiting; red, dry, chapped tongue; pulse frequent, small, compressible; countenance pinched; urgent desire to pass urine; not much pain on pressure over the abdomen, which was tympanitic, except over the right iliac region, which was dull on percussion; no abdominal tumor to be detected. Introduced catheter, after the use of a hip-bath, which gave much ease, but without bringing away any urine. Ordered fomentations with Ol. Terebinth. Introduced up the rectum œsophagus tube nearly a foot, and injected two or three pints of warm water, till the sense of pressure became inconvenient, but without bringing away any feculent motion.

Prescribed small doses of calomel and croton oil, with effervescent mixture, every second hour, also mercurial and camphor frictions every sixth hour. Next day found the patient more exhausted, with constant vomiting, very restless; pain over abdomen more decided, with increased distension; no action from the bowels; passed a little urine; pulse weaker and less frequent; patient quite collected, though very restless. Ordered to continue the mercurial frictions, and the powders in smaller doses, with half a grain of opium, and the effervescent mixture; beef-tea and a little brandy and water as often as tolerated; beef-tea injections, with olive oil, every four hours, with occasional fomentations to the abdo-

men. Third day; moribund, but conscious; rejected all medicine and aliment, cold water alone grateful; pulse almost imperceptible. Patient took one more powder, with a quarter of a grain of Acet. Morph., which quieted the stomach and relieved abdominal pain: died in the night (66 hours after I first attended her) perfectly conscious.

Post-mortem examination 36 hours after death. — Epiploon descending over the cæcum, containing a dense tumor, some six ounces in weight, in its interstices, surrounding and compressing the bowel. When incised the tumor was found to be cephalomatous. The lower ileum, some inches from the ilio-cæcal valve, was much thickened, and contained solid fecula. Mucous membrane dark, coats infiltrated with soft cancer. The cæcum distended with solid fecula. The folds of intestine injected at their free edges. The peritoneum injected with encephaloid deposit underneath; some slight serous effusion.

REMARKS.—How futile are all therapeutics with a *curative* view, how obscure and unsuccessful any diagnostic or *operative* procedure, the preceding case well illustrates. The fatal occlusion of the bowel was *directly* owing to the effects of cold, inducing febrile disturbance and intestinal congestion. The death was more remotely the result of malignant deposit of slow growth. The lower portion of the ileum and cæcum will probably be found the seat of obstruction in most cases of ileus productive of mechanical arrest, where no immediate cause is in operation. Preventive means are the chief safeguard; violent measures useless and objectionable, as aggravating both the disease and the patient's suffering. Surgical operation is rarely admissible, and past experience by no means recommends its further trial.

Carcinoma of the Right Lung.

I was called to visit a woman, aged 74 years, on the 26th of November, 1850. She had been an old servant, of middle sanguine temperament, and highly abstemious habits, some members of her family having died of phthisis pulmonalis. She had had an attack of acute rheumatism some two or three years previously, being subject to so-called asthmatic attacks, and to conjunctival inflammation. About three months before my visit I was informed that she ejected from the mouth a considerable quantity of florid blood; and, a day or two subsequently, took cold from exposure to rain, which brought on this fatal illness. I was told that the medical gentleman in attendance was of opinion that no disease of the lungs existed, but that her

heart was the seat of her ailment. From further queries I learned that she at first complained (after exposure to cold, &c.) of severe pain in the right side, which subsided after a little time; and that, after five or six weeks, her medical man discontinued attendance (resuming it prior to her death), partly as she was averse to ordinary medicines (more homoeopathy!), and because small benefit seemed to be derived from the means used, which consisted of little else than castor oil, and mustard poultices to the chest, with some pectoral mixtures, &c. I found the patient dozing, and was told that she had been and continued to be delirious for some days previously, the delirium being of a low, wandering character. She was roused up, and answered questions, though imperfectly: her posture, which was half-raised in bed, she was obliged to retain, as being subject to paroxysms of orthopnea; her countenance was somewhat sullen; lips of a bright vermilion colour; pupils contracted; head cool, and little action in the temporal arteries. The feet and ankles were slightly cedematous; skin hot, and very dry; pulse about 100, small, compressible, and regular; tongue slightly furred, and readily protruded. There was difficulty of deglutition, and thirst; no pain on pressure over the abdomen, nor was the respiration abdominal; the bowels not being acted upon for some days, and the urine being high-coloured and rather scanty. On exploring the chest (the patient being with some difficulty placed in a suitable position, and otherwise unfavourably circumstanced for examination) the respiratory movements did not present much dissimilarity on either side; being, however, slightly diminished on the right: no dilatation was present on this side, either of the intercostal spaces or parietes generally, which, however, seemed to remain in a partially fixed state, neither contracted nor dilated. On percussing the chest, complete dullness, both from light and heavier percussion, was found to exist, extending from the clavicle to the 6th rib, and from the sternum to the scapula, closely following the inferior boundary of the right lung. The left side of the chest contracted remarkably in clearness, commencing accurately from the left half of the sternum, with the right side. The stethoscope detected little or no breath-sound over the right half of the chest, save a slight whiffling rale near the mid-sternum, and between the scapulae, bronchial respiration and bronchophony being absent, as well as vocal vibration. The respiratory murmur was puerile and slightly rough over the left lung, and the cardiac sounds were natural in situation, extent, and character. There was but little cough, and

slight expectoration, which, I was informed, was never sanguinolent, but opaque and viscid. Such was the previous history and present condition of the patient, collected as well as circumstances permitted. Now there were no less than six distinct abnormal states of the chest which would give the most marked physical aberration here present—viz., dullness on percussion. First—did it arise from pleuritic effusion? The accession of the attack, with pain in the side, and febrile symptoms, without much cough or expectoration, and the absence of bronchial respiration, vocal resonance, or vibration, seemed to favour this conclusion; but there was no intercostal or parietal dilatation from effusion, which most probably there would have been, from the continuance of the attack for three months, unchecked by constitutional treatment. Again; the thoracic parietes performed, though imperfectly, the normal movements; and, although the patient had had acute rheumatism, no organic disease of the heart remained to account for those congestive and effusive sequelae usually resulting from cardiac disease. Moreover, no displacement of the heart took place. Secondly: was the dullness consistent with the existence of hepatization of the lung from pneumonia? Although some previous and present points in the case—such as the probable supervision of pneumonia on hæmoptysis, &c.—might support this supposition, yet its protracted continuance, with undiminished dullness, nearly total absence of all sound derived from the respiration or voice, as well as the very general diffusion of the dullness over the entire right half of the chest, induced me to negative this conclusion.

Thirdly, was this state consistent with cirrhosis of the lung? a pathological condition so well described by Dr. Corrigan, of Dublin. This was negatived by the heart or lung not being dragged over to the affected side of the chest, accompanied with characteristic signs, and by the case being attended with acute symptoms, and still no pectoriloquy or breath sound present.

Fourthly, did the dull sound arise from malignant deposit in the lung, which might have given rise to the hæmoptysis, and congestion of the pulmonary or pleural tissues? But how account, under this supposition, for the great extent of the morbid sound on percussion, and for the absence of bronchial respiration, voice, or thrill? and the aspect of the patient did not strike me as that of carcinoma.

Moreover, fifthly, the patient's age rendered the existence of tubercle to this extent improbable.

Sixthly and lastly, was the dullness on percussion the result of pulmonary hæmorrhage?

hage or apoplexy? This, on the whole, seemed the most likely interpretation of the case. There was, however, no sanguineous expectoration throughout; and could effusion or consolidation of the pulmonary tissue possibly occupy the entire lung? I concluded, finally, that slight pleural effusion existed, as a consequence of preceding inflammation, attended with pulmonary congestion, succeeding to malignant deposit in the lung.

This view taken of the case was interesting more in relation with the diagnosis than as to the treatment, as it was evident that the patient's state was hopeless, and now insusceptible of remedy. A few doses of Hyd. c. Creta, with Pulv. Doveri, followed by Castor oil; a blister on the right side; a supporting diet, with a mixture of Carb. Ammoniac, Tr. Scilla, Tr. Camph. Comp., in Camphor Julep, constituting the treatment prescribed. The patient died two days subsequently, in a fit of orthopnea.

The necropsy (thirty-six hours after death) cleared up much of the obscurity of the case.

On raising the parietes, the right lung was found adherent to the internal aspect of the sternum; it presented a whitish mottled appearance, and felt quite solidified from top to bottom. A vertical section disclosed a nearly uniform and extensive layer or deposit, resembling soft cartilage, and white marble in colour, the growth nearly replacing the pulmonary tissue, and appearing, as Dr. Symonds observes, "to have monopolised all the nutriment sent to the normal tissue, which has in consequence disappeared before it, and of which it has taken the mould."²

A section of the pulmonary tissue, not having any carcinomatous deposit, sunk in water, and seemed much congested, and of a dark colour; the smaller bronchial tubes were obliterated. The left lung was free from deposit, but was slightly congested, though a portion floated in water. Slight effusion existed in the right pleura. The heart was quite healthy, and of normal dimensions; as was the liver, save being a little deeper in colour than usual. No other parts were examined.

We could now account for many of the obscure circumstances attending this case. The perfect and extensive dulness on percussion was produced by the general carcinomatous deposition in the right lung, conjoined with its adhesion to the sternal pleura. Neither bronchial respiration nor bronchophony was heard (no more than in pleuritic effusion, from the non-transmission of vibrations through a fluid medium), in

consequence of the obliteration of the bronchial tubes. But as there was little effusion, no intercostal bulging or distension of the thoracic parietes existed, and the lung continued, though imperfectly, to follow the respiratory movements, the febrile symptoms were accounted for by the congested state of the non-cancerous portions of the right and left lung, and by the slight pleuritic implication. So that a conjunction of the characteristic signs and symptoms of the several affections passed in review, was accounted for in a pretty satisfactory manner by the result of post-mortem inspection, which proved the partial existence of three out of the six states above referred to.

The case affords an instructive instance of the complicated form in which disease may present itself; and forcibly indicates the necessity of our opinion as to the nature of any particular case coming under observation, being based on a comprehensive review and consideration of the past and present state of the patient.

ACADEMY OF MEDICINE, PARIS.

Nov. 20, 1859.

Scarification of the Neck of the Uterus in Leucorrhœa.

DR. MAYER, of Belfort, transmitted an essay on this subject, and on the use of a new scarificator, in symptomatic congestion of the uterus.

The author concluded:—1. That there is a form of leucorrhœa dependent only on uterine congestion. 2. That this form of leucorrhœa requires local depletion. 3. That for this depletion leeches are insufficient. 4. That they may be superseded by scarification. 5. That an instrument which he has contrived for the purpose merits the attention of practitioners.

On the Employment of Impermeable Vaseline in Inflammations of the Skin.

M. ROBERT LATOUR addressed a letter to the Academy, in which he complained of the little notice that had been taken of a communication submitted by him on the above-named subject, in the month of March last. After enumerating the diseases in which the treatment he advises has been found useful, he concludes with the following propositions:—1. That animal heat is dependent on the capillary circulation. 2. Inflammation is an "hydraulic animal fact" subordinate to calorification. 3. To attack inflammation the animal heat must be attacked in its essential elements.

4. The experiments of M. Fourcault have proved that the immediate action of the air on the skin is essential to calorification.

5. The first indication in the treatment of inflammation of the skin is to check calorification by preventing the access of air.

Aneurismal Varix cured by Ligature.

M. ROUX communicated a case of aneurismal varix operated upon successfully. The disease was seated on the left arm, the whole venous system of which it embraced: it dated six years. M. Roux placed a ligature on the brachial artery, both above and below its relations with the tumor. The result had been successful.

M. Roux added the following remarks, deduced from five cases:—Aneurismal varix may be either spontaneous or traumatic: its most frequent cause is puncture of the artery in venesection: it is more frequent on the left than on the right arm.

SURGICAL SOCIETY OF PARIS.

Nov. 27, 1850.

Considerations on Calculi of the Prostate.

M. CHASSAIGNAC made some observations on a case of vesico-prostatic calculus mentioned by M. Vidal at a preceding meeting. The following is a summary of M. Chassaig-nac's remarks:—

In patients presenting calculi in the prostatic portion of the urethra the prostate exhibits a state of atrophy. The calculi are maintained very firmly in the pouch which encloses them. The lateral operation is to be preferred to any other for their extraction, while lithotomy is excluded. In performing this operation, the atrophied state of the prostate must be borne in mind. The calculi must be removed with a scoop, and not with forceps.

M. Vidal divided these calculi into vesical and prostatic, according to their origin. M. Vidal did not concur in M. Chassaig-nac's recommendation to have recourse always to the lateral operation, neither did he disapprove of the use of forceps. A short discussion followed, embracing a repetition of the preceding points.

Medico-legal Considerations on Gun-shot Wounds.

M. RIGAL (of Gaillao) submitted the following observations:—

The questions raised by the case of suicide related to the Society on the 20th inst. by M. Deguise, induced the author to think that a notice of several cases which had occurred in his own practice might be acceptable to the Society. M. Rigal then proceeded to their relation:—

1. Le Sieur Causeé, *propriétaire*, about forty-five years of age, residing at Bernae, had been for several weeks the subject of melancholy; afterwards he became possessed with jealousy and groundless suspicions of thieves. One evening, after having been in search of an imaginary thief, he returned home and seated himself at the fire-side between his wife and their nurse and infant child. While his wife was in the act of stooping forward to prepare his beverage, he placed the muzzle of his double-barrelled fowling-piece to her body and discharged the two barrels in rapid succession, laying her dead at his feet. The murder thus perpetrated, Causeé delivered himself up to justice.

On the following day M. Rigal and Dr. Thomas arrived with the magistrates to make an examination of the body. On the posterior aspect of the right side of the chest, near the inferior angle of the scapula, was a round opening, measuring four or five centimetres (=1.574 to 1.968 Eng. inches) in diameter. Around this opening the skin was burnt, dry, and parchment-like. One of the bullets had pierced the right lung and bruised the heart, and passed out below the left breast: the other charge had fractured the vertebrae and divided the spinal cord. The different course of this charge might be explained by the revolution of the barrels. However that might be, it is clear that two successive shots fired from a fowling-piece at a short distance from the body might produce a single, perfectly round orifice. The burning and desiccation of the skin might have influenced the form of the loss of substance.

The woman's chemise presented *three holes*, of which two were confounded in part of their circumference, while the third was quite distinct and at a short distance from the others. The flannel under-garment presents only two apertures. Thus, while the projectiles had caused only one aperture in the part of the body which they had entered, the garments having been applied close to the body, had retained the traces of two projectiles separated by an interval, the folding and shifting of the garment serving to account for the difference.

M. Rigal observed that it was a point of great interest to determine how far a gun-shot wound is modified by the application of the muzzle of the gun to a resisting point —e.g. the thoracic parietes. Considerable difference of opinion exists on this subject, some persons considering that the gun must necessarily be burst. Experiments to determine the question are attended with too great danger to be made. M. Rigal considered himself, therefore, fortunate to be able to adduce an actual case in the absence of experiment.

2. M. X—, aged thirty-eight years, of a cultivated mind, finding himself in the second stage of phthisis, determined to destroy himself, and for that purpose he placed the muzzle of a pocket-pistol close to his chest, holding it in his left hand over the region of the heart: the ball, however, made no wound, but passed off from the body into the apartment. A second similar attempt was attended with the like results. X— reloaded his pistols, and holding the muzzle of one to his forehead, discharged it, and was astonished to find that he had not effected his intentions. He sought the reason of what he called his misfortunes, and found, as he supposed, that his failure was owing to want of air: he therefore made a crucial incision on his forehead with a penknife—attended, however, with the same ill success. "His precaution had been useless"—"the incision had not been large enough," he said. Accordingly he made fresh and longer incisions! but five successive attempts were not more successful. This unfortunate man then opened the veins of his arms by means of his penknife, and retired to his bed. In the morning he was found bathed in his own blood, but still living. M. Rigal was summoned to him; he was restored from his present condition, but fell a victim to the progress of phthisical disease. He had himself confided the preceding facts to M. Rigal, who found the five bullets in the apartment flattened by having come in contact with hard bodies. The forms of the eschars and wounds on his body bore witness to the truth of his statements. From a consideration of this case M. Rigal draws the following conclusions:—

1. When fire-arms are discharged, under the circumstances above indicated, the air confined in the tube produces a movement of recoil. 2. This recoil will be in proportion to the charge, and to the force and degree of exactness with which the muzzle is placed in contact with the surface of the body. 3. It does not necessarily follow that a wound shall be produced, and if it be, it will not always be found exactly at the spot on which the fire-arm was applied. 4. The gun will not explode if well made, and have an ordinary charge.

M. Rigal referred to cases in which balls have traversed the circuit of the cranium, beneath the integuments, without entering its cavity; also, to those cases in which the fire-arm being held close under the chin, the face is horribly mutilated.

M. Rigal terminated his observations by submitting the following questions:—

If a person be attacked in the dark and have fire-arms discharged in his face, is it possible for him to recognise his assailant by the light of the flash?

This medico-legal problem was suggested by the following case:—A man living in a forest was standing at his door, smoking his pipe, one dark autumn evening; he distinctly heard the click of a flint lock which flashed in the pan, without igniting the charge; he turned towards the direction of the noise: immediately the forest resounded with the sound of a gun, and he exclaimed, "Oh, Gabriel, you have killed me!" He subsequently affirmed that by the flash of light he was enabled to recognise the well-known dress and features of a neighbour. The possibility of the recognition was by the authorities referred to the opinion of M. Rigal, and Dr. Crouzet. The experiments they performed in reference to this point lead them to the conclusion that such recognition is impossible.

MM. LARREY, FORGET, and DREUZE, made some few remarks on M. Rigal's cases and observations, in the course of which M. Forget related a case of attempted suicide by gunshot wound.

ACADEMY OF SCIENCES, PARIS.

Nov. 25, 1850.

Action of the Pancreatic Secretion on Oils.

M. LASSAIGNE forwarded a note, entitled Contributions to the History of the Pancreatic Secretion, in which he adds several facts to those already made known by MM. Bernard and Barreswill,—viz., that the pancreatic juice possesses the remarkable property of forming an emulsion with animal and vegetable fats, and of transforming them into fatty acids and glycerine, at a temperature of $+ 38^{\circ}$ Cent. ($= 83^{\circ}$ Fah.)

M. BERNARD had transmitted to M. Lassaigue a small quantity of pancreatic juice which he had obtained from a dog of moderate size.

The following propositions include the result of M. Lassaigue's experiment on this fluid:—

The action of the pancreatic juice on oils is exercised when at a temperature of $+ 12^{\circ}$ to $+ 15^{\circ}$ Cent. ($= 54^{\circ}$ to 57° Fah.) in the course of a few hours. The acidification takes place equally in various gases,—e. g., oxygen, hydrogen, nitrogen, and carbonic oxide. This change appears to be dependent on what Berzelius named the catalytic force. The pancreatic juice will preserve its alkalinity for several days. Sugar and gum dissolved in this fluid remain unchanged.

New Researches on Disinfecting Agents, and on Substances used for the Preservation of Animal Matters.

1851 transmitted the summary

of his researches on these subjects, from which it appears that volatile substances which are composed of carbon and hydrogen, either simply, or essentially, constitute a class of agents having the special property of arresting the action of moist oxygen. In this category are placed sulphuric ether, chloroform, naphtha, oil of *houille*, crude or distilled oil of *schiste*, acetic ether, benzine, naphthaline, oil of spirit of wood, essence of caoutchouc, essential oil of potatoes, essential oil of bitter almonds, and hydriodic ether.

Animal matters placed in vessels of either of these do not undergo putrefaction. Portions of meat exposed in closed vessels to a mixture of air with the vapour of either, retain their freshness for several months.

M. Robin, following the analogy of the chemical composition of those substances, has discovered a second class of compounds possessing the same properties; these are the binary combinations of carbon, and the metalloids, except hydrogen,—*e. g.*, sulphuret of carbon, protochloride of carbon, nitrate of carbon, &c.

Chloroform and protochloride of carbon preserve also the colour of animal substance, besides preventing their putrefaction, but in this respect are not equal to hydrocyanic acid; while with reference to price and the rapidity of its action, the oil of houlle surpasses all other of these agents.

M. Robin considered that the latter might be employed for embalming, for the preservation of anatomical specimens, for the tanning of leather, for the destruction of insects that attack specimens of natural history, and for the preservation of grain, &c. &c.

Hospital and Infirmary Reports.

GUY'S HOSPITAL.

Extensive Lacerated Wound of the Fore-arm from the bursting of a Cannon.

WILLIAM GRANT, *et. 34*, was admitted into No. 15, Cornelius Ward, August 11th, 1849. He is a man of middle stature, has lived and drank rather freely: states that half an hour previous to admission he was engaged firing a cannon to celebrate a festival: had succeeded in doing so with safety several times, until at last he forced a plug into the mouth of the piece, and then fired it, retiring as usual to a distance of five yards, where he stood with the rod in his hand: the result was an instantaneous bursting of the cannon into twenty

or thirty pieces, one portion of which, weighing about 1½ lb., struck him with great violence on the outer side of his left forearm, causing him to stagger back, but without knocking him down. The coat-sleeve and shirt were torn in shreds, and blood soon began to flow freely: it was bound up tightly, he became very faint, and was brought to the hospital in a cart. On examination there was a large lacerated wound on the dorsal aspect of his left forearm, occupying its middle third, and lower part of the upper third. The extensor muscles were very much lacerated and hanging in loose shreds, with a compound comminuted fracture of the ulna, allowing the finger to be passed freely through the wound, between the radius and ulna, through the interosseous ligament down upon the flexor muscles. Mr. Hilton removed three loose pieces of bone, as also the fractured ends, by means of the chain-saw. The radius was dislocated forwards and upwards, its head resting on the humerus above the external condyle: there was no evidence of fracture of this bone, and Mr. Hilton succeeded in reducing it without much difficulty: the loose portions of ragged muscle were removed by the scalpel, and there was no important hæmorrhage.

The anterior part of the forearm having sustained but little apparent injury, the wrist-joint being sound, the chief nerves and vessels uninjured, the patient himself in the prime of life, and in good health, Mr. Hilton thought it would be proper to attempt to save the limb, notwithstanding that there seemed some probability of the elbow-joint being seriously injured, as evidenced by the necessary laceration of the coronary and interosseous ligaments allowing so extensive a displacement of the radius: accordingly, as the surrounding parts were swollen and contused, the arm was raised on a pillow, a piece of moist lint was applied with slight pressure, by means of compress, to prevent hæmorrhage, and he was ordered two grains of opium immediately.

12th.—He took the opium, but nevertheless had passed a very restless night; at present feels more comfortable; is free from actual pain, but complains of numbness along the back of his arm and hand, extending as far as the first phalanges, including the distribution of part of the radial nerve. The extremities of the fingers, however, retained their sensibility. His tongue is moist, but slightly furred; pulse 82, and rather full; skin moist, and of natural temperature. As he had been accustomed to drink freely, and gave evidence of considerable nervous agitation and unsteadiness in his tongue and arms, he

was ordered two pints of porter. In the evening Mr. Hilton removed the temporary compress; the arm was rather more swollen than yesterday, but the wound as yet looked favourably. Warm water dressing; opium gr. ij. nocte maneque.

13th.—He has passed a much better night, having slept comfortably. There is now slight evidence of constitutional disturbance. Pulse increased to 108, and rather full; tongue furred, but moist, and feels thirsty: the swelling around the wound is still considerable, especially towards the elbow: the lacerated ends of the muscles show a slight tendency to slough: temperature of the limb natural; bowels are confined. Ordered Hydrargyri Chloridi, gr. ij.; Opii, gr. j. statim; to continue the porter, and repeat the opium at bedtime.

14th.—He has passed a good night, and is quite free from pain or uneasiness, the numbness and swelling being both less, and the discharge has assumed a more fetid character: the chief part of the surface of the wound is gangrenous, but a few healthy-looking granulations appear in different parts: pulse 120, and full; bowels moved twice.—Pt.

15th.—He is progressing favourably: the marginal skin, as also the surface of the wound in most parts, having separated, leaving a healthy granulating surface: the head of the radius is now rather displaced, and cannot easily be retained in its proper position: his pulse is reduced to 85, and less full.—P.

16th.—He is doing well: the swelling around is subsiding, and he can extend the fingers slightly. As the granulations looked rather weak, Mr. Hilton thought he would bear more support, and ordered the porter to be increased to three pints per diem, to have middle diet, and continue the opium.

17th.—He has passed a more restless night: there is still a little sloughing from the deepest part of the wound; the discharge has increased in quantity, and is of a dirty-looking, purulent character. Pulse rose to 120; tongue coated with white fur, but moist.—Pt.

18th.—The remaining slough has separated, leaving a healthy granulating surface over every part, whilst the discharge is less offensive and more purulent; the swelling around has now nearly subsided. Tongue quite clean and moist; pulse 90, and natural.—P.

20th.—He is gradually improving, and appears very cheerful; sleeps well; appetite returning; he chiefly complains of lumbar pains, seemingly of a rheumatic character. — Ordered Opii, gr. j. omni nocte.

22d.—There is now a good, healthy-

looking, purulent discharge from the wound, which is gradually filling up; and he is progressing altogether as favourably as can be wished for, only suffering from lumbar pains, which are, on the whole, rather less. Being tired of keeping his arm on a pillow, a splint was applied underneath, and he was allowed to get up.

31st.—The wound is nearly filled up, and cicatrization has commenced in some parts.—P.

Sept. 5th.—His general health seems much improved, and the wound is gradually lessening in size: the head of the radius is still rather displaced, but he can bend the elbow to a certain extent without much difficulty; he soon after left the hospital, and continued to attend as out-patient.

He presented himself again, after an interval of three months, and stated that three small pieces of bone came away before the wound closed over. He can now bend the elbow tolerably well. In pronation of the hand, the fractured end of the upper portion of the ulna projects, but is immediately restored in supination; the radius, although displaced, allows of some rotation; he can flex the finger sufficiently to retain anything of moderate size in his hand; his general health is much improved, and he has gained flesh.

August 8th.—Nearly twelve months since the accident. He has now a very moveable and useful arm; can place his hand on his head, or behind his back—in fact, almost wherever he pleases: he can bend the elbow to a right angle, and can extend it nearly as well as on the opposite side: the symmetry of the limb is in some measure lost. After passing the hand over the olecranon, it dips into a hollow, where the ulna is deficient from two to three inches. Owing to well-adjusted pressure from a pad, which he has constantly worn up to the present time, the fractured ends of the bone, at first very prominent, are now lying in a much more favourable position close to the radius; the lower portion of the ulna is still moveable, and not ankylosed to the radius; the cicatrix is much smaller than could have been expected, and sensation is quite perfect over every part of the arm; he can extend the fingers perfectly, and can flex them sufficiently to grasp the hand with moderate force; the head of the radius is now lying in front of the external condyle, where it can be distinctly felt, and is moveable to some extent: he still wears the pad, which consists of two parts, one encircling the arm above the elbow, connected by a leather strap to the other and most important, which was fastened round the forearm, below the elbow, where it is sufficiently padded so as to make constant pressure on

the projecting fractured ends of the ulna, whilst a space was left between the two portions of the apparatus, so as not to interfere with the movements of the elbow-joint. This had the desired effect of keeping the ends of the bone in a more favourable position, whilst at the same time the patient found it a great support to the arm.

Amongst the many severe cases which present themselves to the notice of the practical surgeon, there are none which require deeper consideration than those of injuries to the extremities, involving, as they frequently do, a question so difficult to determine, whether a limb should be amputated, or an attempt be made to save it; and indeed, when one considers how great a variety of accidents occur from a similar cause, and the somewhat rare occurrence of two cases presenting precisely similar features, it can readily be understood how difficult it would be to draw a line which would enable us to say pointedly, this limb should be amputated, or that should be saved; for, on seeing the state of the patient's arm on admission, and having noted the violent laceration of soft parts, the extent of the fractured bone, the contusion of the surrounding tissues, necessarily the result of a force sufficient to cause such an injury, and also having ascertained an extension of the mischief towards the elbow joint, as evidenced by the laceration of the cordary and interosseous ligaments, allowing such marked displacement of the radius, one's first impression certainly would be that amputation was the only resource, as a means of safety to the patient's life; and such, indeed, was the opinion of many who saw this case at the time: but, on after consideration, I think that amputation, under existing circumstances, would not have been justifiable; for, as Mr. Hilton observed at the time, the most important part had sustained but little injury; the flexor part of the forearm was comparatively uninjured; the chief nerves and vessels were safe, and the wrist-joint was sound; the patient's age was in his favour; his general health had been previously good, and his constitutional powers apparently unimpaired. The justice of these remarks was amply borne out by the progress and termination of the case, which was in reality more favourable than could have been anticipated, as no bad symptoms occurred from beginning to end.

In reference to treatment, it will be observed that stimulants and support were indicated from the commencement. The patient had been accustomed to drink freely, and from the nervous agitation which existed on the day after the accident,

it did not seem improbable that delirium tremens would have been the consequence, if the accustomed stimulus was denied. Such an occurrence was also no doubt prevented by the large doses of opium exhibited. One question yet remains to be considered. Was the limb a useful one after all? This may be best answered by his condition at the present time.

Nov. 27th, 1850.—He has now resumed his work as a cooper for one month, having left off the pad (which he has worn for the last fifteen months) about a fortnight since. The injured arm when compared with the sound one is one inch shorter, and its movements are considerably improved; whilst the large gap left between the ends of the bone, where the muscle was destroyed, is now very nearly filled up by soft tissues. The head of the radius can easily be felt in front of the external condyle, where it is moveable to some extent, and allows flexion of the joint to a right angle, whilst extension is nearly perfect. The flexor muscles have recovered from their former stiffness. He can grasp with sufficient force to hold the handle of his knife in his left hand when at work, and can raise a moderate weight without much difficulty. The fractured ends of the ulna are now in close contact with the radius; though not ankylosed to it; and the only inconvenience he complains of is a slight aching pain over the end of the bone after working some hours, or when the arm is suffered to hang down.

Gun-shot Wound in the Neck.

William Everitt, *et.* 18, was admitted into No. 2, Cornelius Ward, under Mr. Hilton's care, July 10th, 1850. He was in a faint and somewhat exhausted condition, though quite sensible, having been shot in the neck some few hours previously.

It appears that, in company with another man, he had broken into a gentleman's house at Camberwell, had removed some property, and was standing in a stooping posture outside a window, his head and neck being parallel with, though somewhat above the ledge, when the gentleman fired at him from a short distance with a pistol. He immediately fell, but soon recovered himself, and with his companion scaled the garden wall, and made good his escape into the Kent Road, leaving about four ounces of blood on the spot where he was shot. He soon after met with a policeman, said he had been shot by a gamekeeper, and was immediately brought to the hospital.

On examination there was a circular wound on the left side of the neck, situated below the mastoid process, about one inch below and behind the lobe of the ear near to the posterior border of the sterno-mas-

toid muscle, a portion of which the bullet in all probability had perforated. On introducing a probe, it passed in a direction downwards and forwards towards the lower part of the larynx (where a mark was made with nitrate of silver), but no evidence of the bullet, or indeed any foreign substance, could be detected. His neck and chest

were carefully examined with a similar result: the external opening was quite circular, about a quarter of an inch in diameter, its edges being inverted, minutely lacerated, and rather livid, with slight swelling around. His chief complaint was of pain in his left arm, which he attributed to having fallen upon it, but no evidence of external injury could be detected: he also complains of an uncomfortable sensation, almost amounting to pain, on swallowing: respiration, however, is perfectly easy and natural: pulse 84. Ordered Pil. Colocynth. c. Cal. gr. x. statim; Olei Ricini, ʒij. post horas quatuor.

2 P.M.—There has been no hæmorrhage since admission: he now complains of numbness and tingling along the outer and back part of his arm, which suggested that the bullet might probably be lodged somewhere near the brachial plexus: bowels have been opened. As he was the subject of scabies, ordered Ung. Sulphuris, infricand. A bullet from the same mould as that with which he was shot measured five-sixteenths an inch in diameter.

11th.—He has passed a good night: there is rather more swelling around the wound, with tenderness on pressure: he still complains of pain in his arm, and lies most comfortably on the right side. Pulse 116, and rather full. As yet there is no indication to the position of the bullet. Hyd. c. Creta et Pulv. Doveri, ss. gr. v. ter die; Julep. Ammoniac Acetatis, ʒij. ter die. In the evening he seemed more feverish, and complained of numbness over and above the clavicle.

12th.—He is less feverish to-day and has passed a better night, having less pain in the arm. There is now a slight discharge from the wound, whilst the inverted edges are less marked; but the surrounding swelling is if anything increased: he lies chiefly on the affected side, and feels easiest in that position. Pulse decreased to 100, and not so full. Linseed-meal poultice, with Ext. Conium.

13th.—The wound is at present discharging freely, and he is much less feverish, but still complains of pain down the arm and numbness over the acromion: tongue furred, but moist; pulse decreased, to 88; bowels confined. Pil. Col. c. Cal. gr. x. statim: Ol. Ricini, ʒij. post horas quatuor.

17th.—He seems daily improving: the numbness in the shoulder is much diminished, whilst the discharge from the wound is of a more healthy character: tongue cleaner. Sodæ Sesquicarb. gr. x.; Ex. Decoct. Cinchona, ʒj., t. d.

21st.—The numbness has quite left the shoulder, whilst the pain in the arm is very slight. He now complains of pain in his neck along the margin of the trapezius; nothing abnormal, however, can be felt there, whilst the external wound is nearly healed. Bowels confined.—Pil. Col. c. Cal. gr. xv. statim.

25th.—He seems much improved. Appetite returned. Quite free from pain.

30th.—The wound is healed. He feels as well as ever. To be presented.

Perhaps an explanation of the reason why so little constitutional disturbance existed in this case may in some measure be afforded by remembering that the patient's neck was uncovered over that part where the bullet entered, and thus prevented the possibility of any portion of clothing or other extraneous substance being carried into the wound. The direction of a gun-shot wound would depend in some measure on the posture of a person at the time of the shot, also on the speed of the ball, as well as the thickness and resistance of the part it struck. In the present instance the man was in a stooping posture, his neck being parallel with the ledge of a window, and, from the direction in which the shot was fired, one would

have expected the ball had lodged somewhere in the back part of the neck. Such, however, did not appear to be the case, for no evidence of it could be discovered externally; whilst the direction in which the probe passed was quite the reverse; and, rather remarkable, it appeared to pass at first through the posterior portion of the sterno-mastoid muscle, thence under it, downwards and forwards, towards the lower part of the larynx. At that spot where the extremity of the probe could be felt under the skin Mr. Hilton made a mark with the nitrate of silver, so that, in case of suppuration taking place, and not discharging through the wound, it might afford some indication as to the best situation in which an opening should be made. Knowing how a ball may be turned by any slight resistance not directly opposed to it, it has been suggested by several authors that, if the resistance should be greater than the momentum, and offered by an elastic body, the recoil of the ball may be so exact as to return through the same opening by which it entered; and, indeed, a similar opinion was hazarded by a gentleman who saw this case at the time. The conjecture, however, does not seem at all probable, as the character of the wound was decidedly against it, its edges being inverted and minutely lacerated; whereas it seems reasonable to suppose that the small opening made by the swift ball on entering would not have allowed the same to return (its impetus of course being considerably diminished) without everting the edges of the wound, so that the only conclusion one can arrive at is, that the ball still remains buried in the tissues of the body. The period of time during which a foreign body may remain without giving rise to any notable inconvenience is also worthy of notice. Mr. Hilton mentioned an instance which had come under his observation where a bullet had been lodged in the lumbar region for twenty-three years.

involved. It was evident that an obstruction existed somewhere to the return of the venous current from the lower half of the body, involving the portal circulation, but apparently involving much more.

Her own statement pointed to the anasarca of the lower limbs as anterior to the ascites, but in this she was mistaken; and the very considerable amount and long-continuance of the anasarca were unusual: indeed, the chief circumstances indicating the liver as the cause, were pain,—recent pain there,—and a yellow colour of the eyes, and both were calculated to mislead: some, unlike old cirrhosis, were like congestion from obstruction farther on in the cava itself. And it only became evident that ascites was probably the primary, as it certainly was the more important of the dropsical effusions, from the maintenance of a low horizontal position in bed.

The kidneys were never successfully brought into action; and this, I think, is constantly the case in similar instances, even when quite free from disease, simply in consequence of the pressure of the fluid. In corroboration of this view, I may cite the similar instance of ovarian dropsy, where I have observed albuminuria, produced simply by pressure, disappear when that pressure was relieved.

Of the milder purgatives she had plenty, and the want of success attending their employment did not encourage the use of the more violent cathartics in her weak and depressed state.

The question of giving vent to this fluid by tapping was once or twice referred to; but having been employed about the same time in another case, which proved fatal in a very few hours by peritonitis, Dr. Nairne congratulated himself that this course had not been followed.

O. R., *etat.* 15, a girl of quiet habits, was brought up from the country in an advanced stage of dropsy affecting the abdomen and lower extremities, but not extending at all to the upper part of the body; and admitted under Dr. Nairne, on 29th of August, 1850.

The history of the case was obscure: she had had a severe illness of some sort, supposed to have been "a fever," about eighteen or twenty months previously, and had not been thoroughly well since, but had been sufficiently strong to be engaged in farm-work until after the commencement of the present attack, which dated back about twelve months, having begun, so far as she knew, with swelling of the ankles, especially of an evening. The abdomen had begun to swell soon after; and since that had been observed, she had never been entirely free from oedema. She had been under medical treatment during the whole

ST. GEORGE'S HOSPITAL.

REPORTED BY Dr. BARCLAY,
Medical Registrar.

Cirrhosis of Liver and Ascites in a Girl of 15 years of age.

THIS case seems worthy of being placed on record, as well from the rarity of cirrhosis of the liver in so young a female, as from the obscurity in which its history was

period; she had not suffered from pain in the back, nor had had pain in the right side until lately; but a blister had been applied to the right hypochondriac region nearly a month ago. The catamenia had occurred last in June, had been seen twice at irregular intervals last year, and not since.

The abdomen is very tense, communicating to the hand a very distinct sense of fluctuation, and with no hardness. The bowels can be made to float in any direction by turning her on either side, the resonance on percussion always being found at the most elevated situation, indicating that the fluid is not contained in any cyst. The legs are very anasarctous. Pulse quick; tongue coated, but moist. Bowels confined; urine said to be very scanty.

She was ordered to be freely purged with jalap, colocynth, senna, &c., for two or three days.

Sept. 1st.—On testing the urine it is found perfectly free from albumen, but scanty, and of a very deep brown colour, not containing any excess of lithates, nor giving any pink sediment. The heart is also free from any abnormal sound. Ordered to have a draught containing a scruple of acetate of potash every six hours.

5th.—The dropsy has not at all decreased, and she complains of great pain at the top of the right thigh, where there is a small superficial ulcer, with a good deal of redness round, which she accounts for by stating that the skin had burst in that situation some short time previously. This also probably explains a remarkable difference which is now to be observed between the two legs in point of size, the right being larger and harder than the left; for she states positively that, before this occurrence, both legs were of exactly the same size.

The thigh was directed to be propped up with pillows, by which, through gravitation, the distension would be relieved; and local applications were directed by the surgeon to the ulcer. It soon ceased to trouble her.

7th.—A slight attack of epistaxis to-day, accompanied by a sudden discharge of blood from the mouth, which does not seem to have been brought up by coughing: neither was it attended with retching, but has probably, from its dark colour, come from the stomach. The urine to-day, too, has acquired a slight degree of opacity, and does not become clear on boiling with acid; under the microscope it exhibits the presence of numerous blood-globules. To have castor oil, and go on with her mixture.

11th.—Ordered to have a draught every six hours, containing one ounce of decoction of bark, half an ounce of spirit of

mindererus, and a scruple of acetate of potash every six hours.

13th.—To-day she is attacked with severe dyspnoea and pain in the chest, which she refers principally to the region of the heart. Its action is quick, excited, and somewhat oppressed, but no abnormal sound can be made out. Twelve leeches were directed to be applied, and distilled water to be substituted for decoction of bark in her mixture, with the addition of ten minims of tincture of digitalis, and to have house medicine to-morrow.

17th.—She has had no return of the severe dyspnoea, but had a slight attack one evening lately. She is more swelled, both in stomach and legs; the yellow colour has disappeared from the eyes. Ordered to have three grains of blue pill, and one of powdered squill, three times a day, while she leaves off the mixture.

18th.—To-day all the distress has returned. There is pain referred to the region of the heart, with excited and tumultuary action. The swelling of the abdomen and legs is such that she cannot sit up in bed, although the breathing is much interfered with by the upward pressure of the diaphragm. Six leeches were again directed to be applied to the præcordium, and she was ordered to have three grains of calomel and a quarter of a grain of opium three times a day.

27th.—Nothing has occurred worthy of note. To-day the gums have become affected by the calomel. Her general symptoms unrelieved. Her appetite fails, and she is afraid to eat, from the extreme state of distension, which causes the smallest quantity of food to produce great dyspnoea. Still she lies flat on her back, or only inclines to one side or other. Ordered to leave off the calomel, and have a senna draught.

30th.—She has complained, in addition, of pain in the loins. The urine has the same general characters as previously—viz. a certain degree of opacity, which is not removed by boiling with acid, but is not more distinctly albuminous. She is to resume the pill twice a day.

Oct. 7th.—The calomel was omitted after a few days' continuance, and a mixture has been ordered with nitre, nitric ether, and a few drops of laudanum; but she is now beginning manifestly to sink. The face is pinched and anxious, the pulse scarcely perceptible, and her sufferings much aggravated; she can scarcely swallow a little wine which has been ordered.

11th.—Died last evening. She has struggled hard for life. Her end was hourly expected on the evening of the 9th, but she did not cease to breathe till the afternoon of yesterday.

Post-mortem examination 21 hours after death.

General appearance.—Body well-made. Abdomen much distended. Lower extremities very oedematous.

Thorax.—Each pleural cavity contained about half a pint of clear serum. The lungs were much compressed, and slightly congested posteriorly, and there was a good deal of ecchymosis beneath the pleura costalis on either side. The heart healthy; ventricles contracted.

Abdomen.—The cavity of the peritoneum was greatly distended, and filled with clear serum. The liver was small, shrunken, pale-coloured, rounded at the edges, and slightly uneven on the surface, where the investing serous membrane was thickened in some places, and opaque. Its cut surfaces presented some portions of pale but healthy structure, especially at the upper part of the organ, but in the neighbourhood of the fissure, where the great vessels enter the liver, it presented a well-marked specimen of cirrhosis. The gall-bladder was small, and contained a little pale biliary fluid; the coats of the gall-bladder were thickened, and more opaque than usual. Gall-duets healthy. The spleen was small and firm. The kidneys congested, but otherwise healthy.

EXAMINATION FOR THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.

THE examination for the Fellowship took place on the 3rd and 5th inst. There were only four candidates for the honour.

In the first examination on *Anatomy* and *Physiology* the following questions were submitted:—

1. What glands pour their secretions into the mouth? Describe the situation and connections of the parotid.
2. Describe the elbow-joint, and the mechanism by which rotation and supination of the hand is (are?) performed.
3. Describe the position, course, and connection of the intestinum rectum in the male; and mention the peculiarities of its structure.
4. Describe the course of the common iliac artery, its relative position to the parts around on the right and left side, the point of its bifurcation, and course and relative position of the external iliac.

* To Wilks was awarded a gold medal for his commentary on a case in medicine.

5. Describe the distribution of the arteries supplying the abdominal portion of the organs of digestion.

6. Enumerate the parts occupying the upper opening of the thorax, and describe their relative situation.

In the second examination, which was on *Pathology and Surgery*, there were the following questions:—

1. Describe the healing process by adhesion, by granulation.

2. Describe the most frequent causes of suspended animation, their modes of action, and how death is to be averted.

3. Describe the evidences of the presence of a foreign body in the air-passages, the operation for its removal, and the difficulties and dangers which may attend it.

4. Describe the morbid changes which attend the formation and progress of a popliteal aneurism, the operation for its cure by ligatures, and by compression of the femoral artery. How do these two modes of treatment act in the cure of the disease, and what are their respective merits?

5. Describe the effects of rickets on the bones generally and specially: give the treatment of the disease.

6. Enumerate the diseases of the eye in which morbid action originates in the conjunctiva.

ROYAL COLLEGE OF SURGEONS.

GENTLEMEN admitted members on the 29th ult.:—Messrs. A. Hampeon—W. D. Lacy—A. M. Blomfield—G. A. Galland—E. Batly—J. Ringland—H. Lawrence—E. H. Paget.

GEOLOGICAL SOCIETY.

THE following papers will be read at the next evening meeting of the Geological Society, Dec. 18:—

1. On the Epiolitic Rocks of the Venetian Alps. By Prof. A. T. Catullo.

2. On the Mineral Springs of Vichy. By Sir R. I. Murchison, F.G.S., &c.

3. Report on a New Combustible Substance (Pungerite) discovered in Russia.

OBITUARY.

AT Ordnance Place, Chatham, on the 1st inst., Patrick Brodie, Esq., late Assistant-Surgeon 13th Light Infantry.

On the 10th inst., at 63, Hoxton Old Town, George Thos. Heath, M.D., æt. 67.

ADULTERATION OF MILK.

THE *Journal de Chimie Médicale*, Sept. 1850, states that two persons in Paris, carrying on the business of supplying milk to the public, have been sentenced to eight days' imprisonment, and a fine of fifty francs, for adulterating milk with dextrine and water.

Selections from Journals.

DISADVANTAGES OF CHLORIC ETHER AS AN ANÆSTHETIC.

THE chloric ether consists of one part of pure chloroform, with nine parts of alcohol. This, "it cannot be denied," says Dr. Hayward, "derives its power of producing insensibility from the chloroform it contains; and it is difficult to understand how the addition of alcohol can deprive it of its dangerous properties when it is well known that the mixture of this substance with sulphuric ether renders it in great measure unfit for inhalation."

"The advantages which it is said to possess are, that its odour is less pungent and disagreeable than that of sulphuric ether, and that it can be inhaled with little or no inconvenience. At the same time, it must be admitted that it is necessary to use as much chloric as sulphuric ether, and to continue the inhalation for as long a time to produce the desired effect.

"The disadvantages are, that when it comes in contact with the unprotected skin, it acts upon it in the same manner as chloroform. From this cause a patient suffered several months at the hospital, and I believe much more severely than if he had undergone the operation without the ether. I am confident, too, that it is more apt to produce vomiting, and a greater disturbance of the brain and nervous system, causing headache, restlessness and vigilance, which not unfrequently continue for many hours after its exhibition. Perhaps these last symptoms may be owing to the great amount of alcohol it contains.

"I cannot, I confess, divest myself of the belief that chloric ether is an unsafe anæsthetic agent, when I consider that it is simply chloroform diluted with alcohol. It is true, that as far as we know, no fatal effects have hitherto followed its inhalation; but it is also true, that it has yet been used to a very limited extent, and in all the cases in which it has been exhibited that have come to my knowledge, it has been managed with great caution and judgment. But I fear that if it be used with the same freedom that sulphuric is, we shall soon have to record some very different results. We cannot feel confident that it will always be confided to skilful hands only, nor by any means certain that death, when not looked for, may not follow its exhibition."—*The American Journal of the Medical Sciences*, July 1850.

CHEAP MEDICAL TEACHING IN THE UNITED STATES—FREE MEDICAL SCHOOLS.

DR. N. S. DAVIS, Professor of Physiology and Pathology in Rush Medical College, Chicago, has, in an address on "Free Medical Schools," insisted very much on "the inordinate expenses" attending medical education on the present system, and proposes to do away with fees to lecturers, and make medical instruction literally "cheap as dirt." The editor of the *Western Lancet* has so ably dissected this scheme, and exposed the miserable rottenness and corruption at its core, that, did our space permit, we would reprint the whole article. We freely endorse the sentiments of the writer on this subject, and expect the next proposition of Professor Davis will be, in addition to a gratis education, to give the students *oyster suppers on Wednesdays and Saturdays, and turkey and venison dinners on Tuesdays and Fridays*; for surely it will never do to let the poor fellows starve on coffee and "chicken-fixins." "Mens sana in corpore sano" used to be the motto in our school-boy days: to attend six lectures a day is mighty hard work, we think, and few minds will be able to labour that much profitably, unless the powers physical be sustained; and what's the use of all the learning in the world without health and strength, we should like to know? If any thing is to be given away, true benevolence would first see that the objects of her bounty lacked nothing in the way of "creature comforts," and these abundantly supplied; the intellectual wants might next be cared for. The Chicago system reverses this order, and offers the hungry, shivering student, a free lecture on the physiology of digestion, saying, "cat and be filled," or a ditto upon animal heat, as a substitute for woollen stockings and over-coat. The plan is new, but immoral; hence 'twill so necessarily be frowned down in this age of regenerate piety and almost universal charity, so universal that even medical schools are becoming tinctured with it, that we have small doubts as to the result.—Professor Smith, *i New York Medical Gazette*.

8. Childbirth, Diseases of Uterus, &c.	5
9. Rheumatism, Diseases of Bones, Joints, &c.	8
10. Skin	2
11. Premature Birth	35
12. Old Age	47
13. Sudden Deaths	6
14. Violence, Privation, Cold, &c.	28

The following is a selection of the numbers of Deaths from the most important special causes:

Small-pox	27	Convulsions	32
Measles	23	Bronchitis	83
Scarlatina	35	Pneumonia	66
Whooping-cough	50	Phthisis	118
Diarrhoea	21	Lungs	8
Cholera	0	Teething	9
Typhus	43	Stomach	7
Dropsy	16	Liver	14
Hydrocephalus	18	Childbirth	3
Apoplexy	22	Uterus	2
Paralysis	30		

REMARKS.—The total number of deaths was 24 below the average mortality of the 49th week of ten previous years.

NOTICES TO CORRESPONDENTS.

Dr. F. J. Brown's case of Diabetes Mellitus next week.

Dr. Tilt's paper, in continuation, has been received.

Dr. Griffith.—In the following number, if possible.

Dr. Thomas Williams, Swansea.—We are obliged by the communication, and shall have great pleasure in giving it early insertion.

We regret the necessity of being obliged to postpone for another week Mr. Brown's (London Hospital) Case of Reduction *en masse*.

Dr. F. Winslow's correspondence shall be published next week. It reached us too late for the current number.

Dr. Pollock's third paper has come to hand.

Mr. Margetson.—Mr. Tomes's lectures are contained in the 39th and 40th volumes of the Journal, 1846-7. Application should be made to the Publishers.

RECEIVED.—Dr. T. K. Chambers.—The Scotsman.

CORRIGENDUM.—In the case of the Countess of Goerlitz, at page 248, col. 1, line 59, after (833'11 cubic feet Eng.) read "of oxygen equivalent to."

Lectures.

COURSE OF LECTURES
ON
DISEASES OF THE HEART.

*Delivered at St. Vincent's Hospital during the
Session 1849-50.*

By O'BRYEN BELLINGHAM, M.D.

Fellow of, and Member of the Court of Examiners
of, the Royal College of Surgeons in Ireland, and
one of the Medical Officers of the Hospital.

LECTURE XV.

GENERAL SIGNS OF HEART DISEASE.

*Indirect or Secondary Symptoms of Cardiac
Disease (concluded)—Congestion of the
Liver—Congestion of the Intestines—
Epigastric Pulsation the Result of Gastro-
Intestinal Congestion—Epigastric Pulsa-
tion in Nervous, Hysterical, and anæmic
Subjects—Congestion of the Brain—
Influence of Hypertrophy of the Left
Ventricle in giving rise to Apoplexy or
Paralysis.*

Congestion of the Liver.

THE connection which exists between a congested state of the liver and morbid conditions of the heart was alluded to by Corvisart, and has been noticed more or less by succeeding writers. Indeed, next to the lungs, the liver is more liable than any other organ to become congested and enlarged, as the result of cardiac disease; and there are several good anatomical reasons why this should be so. 1st. Owing to the structure of the liver; 2d. To the large amount of blood which circulates through it; 3d. To the blood which reaches it by the vena portæ having already passed through capillary vessels, and having consequently lost whatever influence the contraction of the left ventricle had upon it; 4th. To this blood having to pass through two sets of venous capillaries before it reaches the branches of the vena cava hepaticæ; and 5th. To the returning blood of the liver having to arrive at the right side of the heart against gravity.

Thus the substance of the liver, in general terms, may be said to consist of a close network of capillary vessels and ducts, arranged in lobules, and enclosing in their meshes nucleated cells; the tissue of the organ is soft and yielding, and it readily becomes increased in size when its vessels are distended. Again, the whole of the venous blood from the abdominal viscera (with the exception of that from the kidneys, bladder, and uterus) must pass

through the liver before it can reach the right side of the heart; which large amount of blood circulates through the capillaries of the liver, in addition to that which it receives by its own nutritious artery. The circulation of this venous fluid through the liver must necessarily be slow, in consequence not only of the absence of the influence of the contraction of the left ventricle, but from the large size of the capillaries, and the blood having, as has already been observed, to pass through two sets of venous capillaries.

Now if any impediment exists to the passage of the blood through the right chambers of the heart, owing to disease seated in the lungs, or in the left side of the heart, or if the blood ascending by the inferior cava cannot freely enter the right auricle, the circulation in the vena cava hepaticæ becomes retarded, which reacts through the intermediate vessels upon its capillaries. The capillaries of the vena cava hepaticæ have their origin in the centre of each of the lobules, and the circulation through them being impeded, they, as well as the intermediate vessels, become distended. This constitutes the slightest form of congestion of the liver, and has been termed by Mr. Kiernan "the first stage of hepatic venous congestion." A section of the liver, under such circumstances, presents a mottled appearance, the centre of each lobule having a deeper colour than the rest.

When the impediment to the return of the blood to the right side of the heart increases, or when the former condition has lasted for some time, the capillaries of the vena portæ, which occupy the circumference of the lobules, next suffer. The blood in both sets of capillaries being retarded, they become now distended, constituting a still more advanced stage of congestion of the liver; or, what Mr. Kiernan calls "the second stage of hepatic venous congestion." Here "a section of the liver presents likewise a mottled appearance, but now the pale portion will be in spots."

Both sets of vessels may be congested without the function of the liver being impaired, or without any considerable impediment to the secretion or escape of the bile. In many cases, however, when the congestion has lasted long, and the impediment to the return of the blood to the right side of the heart is considerable, the biliary plexus, and the minute ducts which ultimately form the excretory duct, suffer from the pressure; the bile is prevented from freely escaping, it accumulates in the lobules, and biliary is superadded to sanguineous congestion. A section of a portion of the liver will then present the ap-

pearance with which we are familiar as *nutmeg liver*.

Congestion of the liver may therefore be limited to the ramifications of the *venae cavae hepaticae*, or it may extend to the capillaries of the *venae portae*; or the two forms may be combined, as we have seen, with biliary congestion. The first has been termed by some "a passive form of congestion;" the second, an active form; but, when congestion of the liver depends upon cardiac disease, it is always of the passive form. The congestion of the liver may be partial, and occupy only a portion of the organ, or it may engage the entire viscus. This cannot occur without occasioning an increase in the size of the organ, which will be in proportion to the degree of the congestion; to the increased amount of blood contained in the distended vessels: to the length of time the causes which produced it have been in operation; and to the condition of the liver at the time. "In young subjects, and in persons in whom the liver is healthy, and its capsule thin, Dr. Budd* observes, the liver will necessarily enlarge much more for a given force of distension than in persons in opposite circumstances." "When the liver (he adds) has become unnaturally firm and tough, by the interstitial deposit of new fibrous tissue, an impediment to the free passage of blood from it towards the heart, unless it be long continued, will produce but little increase of its size; but it will exert the same, or even greater pressure on the other elements of its texture, and be as apt, therefore, or even more apt, to cause secondary biliary congestion."

"In habitual, and particularly in permanent mechanical hyperemia of the liver, the vessels of the liver, as well as the trunk of the *venae portae*, and the branches from which it arises, are found (Rokitansky† observes) dilated and varicose." Habitual hyperemia of the liver, he adds, is apt to be followed by hypertrophy, and as a consequence of an increased production of portal blood, and an exaggeration of its peculiar qualities, the nutmeg liver may result, which again may give rise to granular degeneration of the organ.

The size which the liver may attain under these circumstances is remarkable: it sometimes extends downwards to below the umbilicus; anteriorly it forms a swelling evident sometimes to the eye, but always perceptible to the hand, while its enlargement upwards causes it to encroach upon the right lung. It must be borne in mind, however, as observed by Dr. Clendinning,‡ that the liver may be enlarged,

and yet not extend below its normal limits. "A large liver, well sustained superiorly, or strongly pressed upwards by tympanitis, or ascites, might pass (he observes) for small or normal; and a small liver, pushed down by emphysema, or pleuritic effusion above, or by stays outside and around, might pass for abnormally large." The actual size which the congested liver attains may, in general, be pretty accurately determined by percussion of the hepatic region.

Enlargement of the liver, the result of congestion, may usually be distinguished from enlargement of the organ from other causes by the liver preserving its normal shape, which is more or less altered in diseased states of the organ, as well as by the suddenness with which the enlargement supervenes and subsides again under treatment. Indeed, the rapidity with which the liver enlarges in some of these cases, and the great increase in size which the organ attains, have sometimes excited an unnecessary degree of alarm in the mind of the practitioner.

When the congested state of the liver has caused considerable increase in size of the organ, the enlargement upwards, which is sometimes from two to three finger-breadths above its normal limits, and as high as the inferior angle of the scapula, or above it, will impede the descent of the diaphragm, and will cause the left side of the thorax to be encroached upon, by which, as M. Gendrin* observes, the dyspnoea under which the patient ordinarily labours will be much aggravated. In addition, the patient usually complains, more or less, of an uneasy sensation in the hepatic region, particularly of a sense of weight: he does not suffer from pain unless pressure is made upon the part, and but seldom even then.

When biliary is combined with sanguineous congestion, the secretion of bile may be interrupted, or its escape may be impeded, owing to the pressure exercised upon the biliary plexuses and interlobular ducts, or to the swelling from congestion of the mucous membrane lining the ducts themselves. The patient will suffer from various symptoms of gastric derangement; as thirst, loss of appetite, vomiting, costiveness, or diarrhoea, with colicky pains, followed by jaundice in a slight or more marked degree, and frequently with diminished secretion of urine. "The gastric derangement which ensues in such cases has a pernicious reaction," Dr. Furnivall* observes, "on the original disease, the gastric irritation adding to the cardiac irritation and aggravating

† Lancet, 1846.

the paroxysms of dyspnoea, as well as exciting them; while the retention of those matters which should be excreted from, and by the agency of the liver, deprives us of one of our principal means of relieving the load of labour which is imposed on the heart." Frequent attacks of, or the long continuance of congestion of the liver, are followed by permanent increase in size of the organ, by congestion of the mucous lining of the alimentary canal, and by hæmorrhoids, or, in aggravated cases, by hæmatemesis; and when the patient's constitution has become much enfeebled, ascites generally sets in.

Any form of cardiac disease which directly or indirectly occasions an impediment to the return of the blood ascending by the inferior cava may give rise to congestion of the liver: the forms of cardiac lesion with which it is most frequently associated are—1st. Considerable contraction of the mitral orifice: here congestion of the lungs always precedes the hepatic congestion. Next in frequency, it occurs in cases where the tricuspid orifice is enlarged, and free regurgitation occurs at each ventricular systole; here the lungs are not engaged, but the venous system generally is engorged. Lastly, congestion of the liver is frequently associated with dilatation of the ventricles, with or without thinning of their parietes; this is frequently associated with a state of the tricuspid orifice permitting free regurgitation: here the congestion is partly due to this cause, and partly to the impediment to the passage of the blood through the chambers of the heart, and partly to the pressure exercised upon the ascending vena cava, as it is about to enter the right auricle, by the enlarged organ.

Congestion of the liver is occasionally consecutive to lesions of other organs beside the heart. This is not the place, however, to delay upon it; it will be sufficient to observe, that in any diseased condition of the lungs in which the pulmonary circulation is impeded congestion may ensue. Among these, pulmonary emphysema is one of the most frequent. The latter condition itself, however, is no unfrequent accompaniment of diseased states of the heart, and, when congestion of the liver occurs, it may depend as much upon it as upon the emphysematous state of the lungs.

Congestion of the Intestines.

The portal vein, we know, receives the blood from the superior and inferior mesenteric veins, from the splenic and gastric veins; consequently the blood returned from the spleen and pancreas, from the small and large intestines, must pass through

the liver before it reaches the right side of the heart. It is easy, therefore, to understand that if congestion of the liver occurs it will react upon the *arrière* current of blood, and, if long continued, that congestion of these organs will ensue. Hence congestion of the intestines is necessarily a secondary lesion to congestion of the liver, and will not be liable to occur in the cases we are considering unless congestion of the liver has preceded it; and, it is to be regarded as purely the result of a mechanical obstacle to the return of the venous blood from these parts.

In the slightest form, where the free return of the venous blood from the gastro-intestinal mucous membrane is merely impeded, the venous trunks simply become congested. When the impediment is greater, or the causes have been longer in operation, along with this state of congestion of the veins, "an injection of the small vessels in streaks, stripes, patches, or points, with opacity of the injected parts, will," Dr. Copland* observes, "be found; and, in the highest degree, a partial effusion of blood into the sub-mucous cellular tissue, forming ecchymoses, or into the cavity of the part, colouring red the matters contained therein." "The mucous membrane lining the intestines, or even the entire membrane of the intestines, may present," Rokitsansky† remarks, "an uniform reddish-black colour, the tissue being saturated with blood, and no injection of blood-vessels being distinguishable: the larger vessels, and particularly the venous trunks, are distended even as far as the mesenterics, and overcharged with blood. In either case hemorrhage may take place into the cavity of the intestines."

The simple form of congestion, when temporary, is not accompanied by any prominent symptom. When the congestion is more marked, when it has persisted for some time, and when the impediment to the return of the venous blood is greater, the train of symptoms which are laid down as characterizing dyspepsia set in, and the patient may refer all his complaints to the abdominal complication, so that it is possible the diseased condition of the heart might be overlooked. "Congestion generally," as Dr. Williams* observes, "impairs the vital properties of internal organs; natural contractility and sensibility are lowered, but pain, spasm, and morbid sympathies are often excited, although in a manner much less distinct and constant than in inflammation or determination of blood.

When the gastro-intestinal mucous mem-

* Dict. of Pract. Medicine.

† Path. Anat. vol. ii.

* Elements of Medicine.

brane has been long or considerably congested, its functions are more or less impaired, and its secretions, as the result, may be either increased or diminished, or vitiated; and according as the gastric mucous membrane, or that lining the large and small intestines, is particularly engaged, the symptoms will vary somewhat. Thus, when it is limited to the stomach, we may have nausea, vomiting, loss of appetite, and epigastric pain; when the mucous membrane lining the intestines is much congested we shall have flatulent distension, irritation, pain, and constipation, or diarrhoea, according as the secretion is increased or diminished, or altered; when the lower portion of the large intestine is congested we may have hæmorrhoids in addition.

The retardation of the circulation in the minute veins and capillaries, and the congestion of the mucous membrane which is the result, may be relieved in part by the transudation of the serous or aqueous parts of the blood, giving rise to diarrhoea with watery stools; or, by the escape of blood itself upon the mucous surface, giving rise to hæmatemesis; frequently by more or less copious discharges of blood from the hæmorrhoidal vessels. The secretion of urine is almost always at the same time diminished, and ascites usually begins to show itself at this period—always, however, preceded by anasarca of the lower extremities.

Epigastric Pulsation.

When hepatic is combined with gastro-intestinal congestion, and the impediment to the return of the venous blood is considerable, this must react upon the arteries which supply these viscera, and, through the celiac axis, and superior and inferior mesenteric arteries, upon the abdominal aorta at its upper part; the pulsation of this vessel becomes more distinct and stronger, constituting one variety of epigastric pulsation, and resembling the form described by Dr. Faussett,* and which was referred by him to local or visceral congestion, or to sub-acute inflammation. This variety of epigastric pulsation is accompanied by "pain on pressure at the epigastric region, or towards the umbilicus, with considerable fulness at the part; the digestive organs are always deranged, the bowels torpid, and the feet cold. The pulsation is most severe towards the afternoon, or soon after dinner, and is accompanied by a sense of vital depression. On auscultation a loud whizzing sound is heard."

A pulsation of the abdominal aorta, or its immediate vessels, which is symptomatic

of inflammatory disease in the abdomen, has been described by Dr. Stokes.* It consists in "a throbbing generally commensurate with the disease; removed by treatment calculated to relieve enteric inflammation, and aggravated by everything which will increase this affection." "In other words, we may have (he observes) from enteritis or peritonitis a throbbing of the abdominal aorta, or its vessels, perfectly analogous to the morbid action of the radial artery in whitlow, or of the carotids or temporal arteries in cerebritis." The diseases in which this pulsation was observed were gastro-enteric fever, peritonitis, and fever after corrosive poisoning.

A pulsation in the epigastric region which is evident to the eye, and perceptible to the hand, and of which the patient himself is conscious, is not unfrequent, however, under other circumstances. In describing the normal position of the heart, we saw that this organ rested upon the cordiform tendon of the diaphragm: now if the sternum is short, and the heart's action strong, there is no more difficulty in understanding how the heart's impulse may be felt in the epigastrium than there is to account for the impulse communicated to the abdominal parietes in the act of coughing; while if the heart itself is enlarged, or if the volume of the lungs is increased, and the heart is pushed somewhat downwards, as happens in emphysema of the lungs, its pulsation will be still more likely to be felt in the epigastrium; as the latter condition of the lungs is in general associated with some enlargement of the right cavities of the heart, particularly if it has persisted long: the epigastric pulsation is usually well marked in such cases. This form of epigastric pulsation is felt high up in the epigastric region; it is an undulatory movement, though quite perceptible to the hand placed upon the part, and is evidently produced by the heart itself. It usually occasions less distress to the patient than some of the other forms, and we are seldom called upon to treat it alone.

Nervous and hysterical pulsation.—Another kind of epigastric pulsation which is observed in subjects in whom the heart and lungs are both perfectly healthy occurs in nervous and hysterical individuals, particularly females. It is nothing more than the pulsation of the abdominal aorta communicated to the parts resting on it, owing to the action of the heart being temporarily increased. The pulsation is most marked below the epigastrium, and the impulse communicated to the hand is a short, smart jerk, very unlike that of aneurism. On auscultation a short whiff is audible, par-

* Dublin Journal of Medicine, vol. ii.

* Ibid. vol. v.

ticularly when the stethoscope is pressed firmly upon the part. This form of epigastric pulsation has remissions, or complete intermissions, and is aggravated or brought on by mental excitement, deranged digestion, or intemperance. The pulsation is usually perceptible to the patient, and is sometimes a source of considerable distress to him.

Anæmic pulsation.—A pulsation in the epigastric region communicated by the abdominal aorta, which occasionally complicates cardiac disease, occurs in anæmic subjects, particularly where this state has been brought on by profuse discharges of blood. The pulsation is strong, abrupt, and bounding, and often accompanied by a short, whizzing murmur, leading sometimes to the suspicion of aneurism. The pulsation is evident to the eye, as well as perceptible to the hand, is most marked below the epigastrium, and is, in a great measure, limited to the line of the artery. In such cases a similar pulsation and a similar sound are usually audible in the large vessels which come off from the arch of the aorta.

Many years since Dr. Baillie* called attention to a form of epigastric pulsation of which he had met some examples, and which probably belongs to some one of the forms already noticed. He observed it in persons about the middle period of life, most frequently in the male; the pulsation, which was often visible to the eye, was stronger in some subjects than in others, varied in strength at different periods, and was usually most marked in the horizontal posture. He believed it to be connected with deranged digestion and an irritable constitution. It is apt, he observes, to cause a good deal of unnecessary anxiety in the patient: it does not depend upon any diseased condition of the artery, for he has known it to continue well marked during twenty-five years without the health suffering. In two instances in which he had the opportunity of making a post-mortem examination, the artery was found to be perfectly healthy.

Pulsation communicated to abdominal tumors.—Tumors, or diseased states of some of the abdominal viscera—as of the pylorus, mesentery, or omentum, or air or feces confined in the transverse colon—not unfrequently have an impulse communicated to them, where they rest upon the aorta below the diaphragm. The pulsation is both evident to the eye and perceptible to the touch, and has sometimes been mistaken for aneurism. It may always be distinguished by the nature of the impulse, which wants the heaving character of the

impulse of aneurism in this situation; by the absence of bruit, or by its different character; by the mobility of the tumor, by the previous history of the case, and by the absence of pain, and of the other signs of abdominal aneurism.

Congestion of the Brain.

That a connection exists between organic disease of the heart and cerebral disease was noticed so long ago as the time of Morgagni; many clinical observations have been since brought forward to prove it, and abundant evidence of the fact has been, within the last few years, adduced by Dr. Clendinning,* by Dr. Burrows,† and Dr. Law.‡

The circulation in the brain may be disturbed in more than one way, as the results of disease of the heart; thus—

1. The blood may be transmitted to the brain in increased amount, or with undue force, by an hypertrophied left ventricle.

2. There may be an impediment to the free return of the venous blood from the brain to the right side of the heart, owing to disease of the latter organ.

3. The blood may not undergo the necessary changes in the lungs, owing to disease of the valves or orifices of the heart, when a mixture of venous and arterial will be transmitted to the brain.

4. The blood may be transmitted to the brain in deficient quantity, as pointed out by Dr. Law, owing to obstructive disease of the orifices of the left side of the heart.

Lastly. Independent of disease of the heart, the blood itself may be thin, watery, and deficient in some of its constituents, as in anæmia; or it may be rich, and quickly formed, as in plethora.

Writers upon diseases of the heart have laid considerable stress upon the influence of hypertrophy of the left ventricle, in causing cerebral congestion, by its transmitting the blood in increased quantity, or with augmented force, to the brain. The arteries which supply the brain run a short course from the arch of the aorta, and they receive, almost immediately, the force of the impulse of the left ventricle; the circulation in the head and face is consequently active, indicated by the greater heat of these parts than of the extremities. Hence, we should expect, that when the left ventricle is hypertrophied and dilated, cerebral congestion would be likely to ensue; but in many instances hypertrophy of the left ventricle, with or without dilatation of its cavity, is itself a secondary lesion, and the result of some impediment to the passage of the blood through, or out

* Croonian Lectures, MEDICAL GAZETTE.

† Disorders of the Cerebral Circulation.

‡ Dublin Journal of Medicine, vol. xvii.

* Trans. of College of Physicians, vol. iv.

of the chambers of the heart. Hence, although the heart's action may be very strong, the pulse is often weak under such circumstances; showing that the strength of the current is not necessarily augmented, or that the amount of blood transmitted by the ventricle is not always increased when the left ventricle is hypertrophied, and its cavity dilated.

In considering congestion of the liver, we found that one effect of congestion was to cause an increase in the size of the congested organ; and we can readily understand that such a delicate organ as the brain, which is enclosed within solid bony walls, could not undergo even slight enlargement, without the cerebral substance and nerves suffering compression.

That injurious effects do not more frequently ensue, has been explained by Dr. Burrows, as follows:—1st. "Owing to the great development of the venous system within the cranium and spinal canal, which affords a ready exit for the redundant blood;" and 2dly, "Owing to the existence of the cerebro-spinal fluid." This fluid he has shown to play a most important part, as—"by its capability of oscillation between the ventricles of the brain and the spinal canal, it compensates for variations in the quantity, or tension of the circulating fluids of the brain. When by increased action of the heart more blood than common is thrown upon the cerebral vessels, the cerebro-spinal fluid subsides into the spinal canal, and injurious pressure upon the cerebral pulp is thus, within certain limits, abated; and on the other hand, if less blood than usual pass into the brain, the fluid rises into the cranium, and the equilibrium of tension is preserved."

Although cerebral congestion may be the result of hypertrophy of the left ventricle, this state is even more likely to ensue, if there is any impediment to the free return of venous blood from the brain. In a state of health this fluid readily returns from the head, being assisted by gravity, and any thing which interferes with it is quickly felt; thus, if the head remains for any length of time on a plane lower than the body, symptoms of cerebral plethora will ensue; as the internal jugular veins are not provided with valves, there is no provision to prevent the reflux of their contents towards the brain. Indeed, persons partly asphyxiated by submersion, or in a state of stupor from intoxication, have often been deprived of life by being carelessly removed in a position which allowed the head to hang downwards.

"Pathologists hitherto have," Dr. Law* observes, "almost entirely confined their

attention to the excess of the normal quantity of blood, or the congestion produced in organs by disease of the heart, but have overlooked the deficiency that must necessarily result to other organs, and consequent hurt to their nutrition and function." He was the first to call attention to the effects of a diminution of the supply of blood to the brain; and he has shown that "ramollissement of the brain occurs in connection with diseases of the heart, whose effect is either directly or indirectly to diminish the flow of blood to the head;" and that "this cerebral lesion may be connected with either disease of the aortic and mitral valves; particularly with considerable contraction of the latter orifice.

When cerebral congestion arises under any of the circumstances mentioned, the patient will suffer from headache, vertigo, tinnitus aurium, or ocular spectra; vague sensations about the head, of rushing, heat, and noise, &c., will be experienced, or heaviness of the head and drowsiness will be the most prominent symptom; the face may be flushed, or the cheeks and lips congested, or it may on the contrary be very pale. "In some instances," Dr. Furnival^o observes, "headache is early complained of, and is both severe and long continued. This is doubtless caused by cerebral venous congestion, and it and other cerebral symptoms have been sometimes so prominent as to mask and to draw attention from the original and originating disorder." When the venous blood is not entirely converted into arterial in the lungs, a mixture of venous and arterial blood is conveyed to the brain, evidenced by drowsiness and stupor, or by wandering of the mind, and a transitory and sometimes pleasing kind of delirium. The latter results are not, however, observed as often as might be expected; the majority of those who die of cardiac disease preserve their intellects perfectly to the close.

Apoplexy and paralysis are considered by several writers to be direct results of hypertrophy of the left ventricle. Thus Dr. Hope, in the *Cyclopædia of Medicine*, and subsequently in his work on *Diseases of the Heart*, remarks:—"Instances of apoplexy supervening upon hypertrophy have been so frequently noticed, that the relation of the two, as cause and effect, is one of the best-established doctrines of modern pathology. Eight or nine cases of suddenly fatal apoplexy, and numerous cases of palsy from hypertrophy, have within a few years fallen under our observation." "Whence we are led to the conclusion, with MM. Richerand and Ber-

* Dublin Journal of Medicine, vol. xvii.

* Lancet, 1846.

tin, that hypertrophy forms a stronger predisposition to apoplexy than the apopleptic condition itself."

It appears to me, however, that the effect of hypertrophy of the left ventricle upon the brain has been overrated; and although in many cases of apoplexy or paralysis, terminating fatally in individuals advanced in life, the ventricles are found to be hypertrophied, yet we usually find the coats of the arteries of the brain to be likewise diseased; in addition, the valves at the left side of the heart are also diseased, by which the return of the venous blood from the brain had been impeded. It is to this latter condition, in connection with a morbid state of the coats of the arteries of the brain, that the majority of the cases of this kind should be referred. Indeed, Corvisart, no mean authority, goes still further, and says, that he never saw organic disease of the heart directly occasion apoplexy and death. "I have," he says, "many times, in cases of this kind, seen all the vessels of the brain, and particularly the sinuses, gorged with blood, but I have never met with extravasation of blood either in the substance of the brain or in its cavities." "In several of the cases related elsewhere the death was sudden; I cannot, however, he adds, assert that I have ever seen a single case of apoplexy which was evidently the result of cardiac disease."

[Conclusion of the First Part of the Course.]

COLLODION APPLIED TO BURNS.

DR. LIMAN, of Berlin, states that he has found collodion a most excellent application to burns. He has applied it in many cases with the best results. He states that it allays the smarting, forms a protective covering, which excludes the action of the air, and is so exactly adapted to all parts that no other dressing is required. The first application is attended with some pain, but is soon followed by alleviation of the suffering, and the cure proceeds steadily without pain. Dr. Liman applied the collodion with a hair-pencil, covering the entire surface, and daily reapplying it to the fissures and uncovered parts. Dr. Liman relates one case in which it was applied in an extensive burn with immediate advantage, and ultimately a speedy cure, without remaining contractions of the integuments. — *Casper's Wochenschrift*, 1850.

. We can confirm Dr. Liman's recommendation, having found collodion equally serviceable with the author in burns, and more especially useful with children, on whom it is often difficult to retain ordinary dressings.

Original Communications.

CASES, WITH REMARKS, ILLUSTRATING THE ASSOCIATION OF CHOREA WITH RHEUMATISM AND DISEASE OF THE HEART.

BY WILLIAM SENHOUSE KIRKES, M.D.

Licentiate of the Royal College of Physicians; Demonstrator of Morbid Anatomy, St. Bartholomew's Hospital.

(Read before the Abernethian Society, March 7th, 1850.)

[Concluded from p. 1009.]

For the reasons stated at the commencement of this paper, I shall refrain from entering into any discussion of the several theories advanced in explanation of the occurrence of nervous phenomena in the course of acute rheumatism. The details, however, of some of the cases I have narrated suggest a few remarks on the principal alleged cause of the development of these nervous symptoms during rheumatism—viz. the existence of some inflammatory affection of the heart, but especially of the pericardium. Now, admitting, as I do most fully, the influence which acute inflammation of the heart or its membranes no doubt frequently exercises in inducing the most varied disorders of the nervous system, and believing that the cardiac complication in articular rheumatism has a large share in the production of chorea, or other nervous disorders which may arise in the course of the attack, yet there appear to be some circumstances favouring an opinion that such inflammatory affection of the heart, or at any rate of the pericardium, is not essential to the development of any of the nervous symptoms in question. The two principal circumstances in favour of such an opinion afforded by the cases I have narrated, and by others presently to be noticed, are first, that chorea occasionally arises in the course of articular rheumatism without the existence of any positive evidence that the heart or pericardium is inflamed; and second, that, as in Cases III. and V., chorea is sometimes developed first, the rheumatism, with or without cardiac complica-

tion being only subsequently super-added.

The two facts just mentioned,—namely, the occasional occurrence of chorea in articular rheumatism uncomplicated by any decided cardiac affection, and the occasional occurrence of chorea *previous* to the onset of rheumatism or of any affection of the heart, naturally suggests an inquiry whether there is not some more general cause for the association between the chorea and the rheumatism than that ascribed to an affection of the heart or pericardium. Apparently impressed with these, and other similar facts, irreconcilable on any previous explanations, Dr. Begbie has recently advanced a very ingenious theory on the subject.

He suggests that the same diathesis or morbid condition of the blood which gives rise to rheumatism, may give rise also to chorea; and he founds his opinion on a fact which I have myself also several times noticed, that out of the same family one member may be affected with chorea, another with rheumatism, while a third may be the subject of both these affections. In instances of this kind the tendency usually seems to be hereditary, one or other of the parents having generally manifested a liability to rheumatism. This view, that the same diathesis may lead to the occurrence either of chorea, of rheumatism, or of both, as the case may be, has many circumstances in its favour, while it explains difficulties which on other hypotheses are inexplicable, and reconciles many facts otherwise opposed to each other, especially the occurrence of chorea previous to the onset of the rheumatic attack. Moreover, it receives the support of Dr. Watson,* and also seems to accord with the observation of Dr. Todd, that "many of the patients who suffer from chorea are of a rheumatic diathesis."†

However inclined one may feel to agree in the general probability of such an explanation of the occurrence of chorea in rheumatism, it seems to me, nevertheless, that there are still several interesting facts to which too little attention has hitherto been paid in the investigation of this subject, especially as these facts appear to help to a better understanding of the associa-

tion in question. While examining this subject it occurred to me that much information might be gained by collecting a number of cases from various authentic sources, and arranging them in a tabular form, constructed so as to show at a glance all the important points in each case. I have therefore brought together 36 cases in which symptoms of chorea were observed in connection either with articular rheumatism alone, or with acute disease of the heart alone, or with rheumatism and cardiac affection combined. (See p. 1052).

On analysis of these 36 cases it will be seen that the chorea was more or less closely associated with rheumatism in 33, while in the remaining 3 there was recent disease of the heart without any affection of the joints. The latter number might have been considerably increased had I included in the table all cases of simple chorea in which an endocardial murmur was heard; but these were purposely omitted, as not seeming to bear on the subject in hand; for it is a question how far in such cases the murmur is dependent on actual organic disease of the heart. In each of the three cases I have given, however, there was distinct evidence of cardiac disease, recent pericarditis in two (1 and 18), and affection of the mitral valve in the third (25).

The next point of interest in the analysis which may here be noted refers to the total number of cases in which there was disease of the heart. Unfortunately this point cannot be determined with certainty; for in 5 of the cases (10, 30, 31, 32, 34) the condition of the heart is not stated, while in three others (4, 21, 24) there was no positive evidence either for or against any cardiac affection. Excluding these doubtful cases, however, we have still twenty-eight in which the state of the heart was noted; and of these we have strong evidence for believing that the heart or its membranes were affected in all but two (13, 23). This very large proportion shows the important share which the cardiac affection doubtless takes in the development of the nervous phenomena: yet the existence of even but two cases of chorea and rheumatism, unaccompanied with disease of the heart, prevents the conclusion that the cardiac complication is invariably an essential element in the production of the nervous symptoms. Besides, it must be remembered that at

* Practice of Physic, 3rd edit. Vol 1, p. 663.

† LONDON MEDICAL GAZETTE, 1846, p. 664.

least in three of the cases (21, 22, 35), the symptoms of chorea ensued before either the rheumatism or affection of the heart appeared. Hence, I think, we may conclude from this part of the analysis, that chorea may be associated with articular rheumatism alone, or with disease of the heart alone, that neither are essential to its occurrence, while it is from the combined influence of the two together that it is most likely to be developed.

On examining into the nature of the cardiac affection in the twenty-six cases in which the heart was said to be diseased, we find in

10 cases, effects of both endocarditis and pericarditis (2, 8, 9, 16, 17, 19, 20, 22, 27, 36).

11 cases, effects of endocarditis alone (5, 6?, 7, 12, 14, 15, 25, 26, 28, 29, 35).

5 cases, effects of pericarditis alone (1, 3, 11, 18, 33).

The endocardium, therefore, presented evidences of disease in no less than twenty-one out of these twenty-six cases, the pericardium only in fifteen. Therefore, if the mere weight of numbers might determine whether affections of the endocardium or of the pericardium were the most likely to be associated with symptoms of chorea, the verdict would be in favour of the former. And such verdict may, I think, be substantiated by several other not unimportant particulars; for, having found the endocardium affected in so large a proportion of these cases, we may be led to inquire whether there is any reason for believing that it might have been affected in the remaining five cases also. In one of these cases (18) the mitral valve was said to be "somewhat thickened;" in the remaining four the condition of the endocardium is not named, and therefore, perhaps, it ought to be inferred that it was sound; but when it is remembered how slight the effects of endocarditis frequently are, consisting only of a few minute beads of lymph along the borders of one or more valves, which might be easily overlooked after death, while their auscultatory signs during life would be masked by those of the pericarditis which existed in all the cases, and that in the fatal cases attention would probably be directed chiefly to the extensive disease presented by the pericardium, especially in cases 1

and 3, which occurred at periods (1821 and 1824) when the appearance of minute granules on the valves of the heart would have attracted much less attention than at the present time, and if seen, might have been deemed unworthy of note,—we may conclude that the non-existence of endocarditis is at least not proved in any of these cases. We might, indeed, go even further than this, and conclude, not unreasonably, that the endocardium was probably affected in one or more of them, remembering "that pericarditis is more frequently found in combination with endocarditis than alone."* It may, perhaps, be thought that, by parity of reasoning, the absence of pericarditis in those cases in which its existence is not stated ought to be considered as also unproved; but the likelihood of the disease being overlooked, either before or after death, is so much less in the case of pericarditis than of endocarditis that this mode of reasoning could have but little weight.

Since, therefore, we have tolerably strong proof that the endocardium was affected in twenty-one out of the twenty-six cases in which the condition of the heart was stated, and some reason for believing that it might be affected in some of the remaining five; while, on the other hand, we have proof of the pericardium being affected in only fifteen, and no positive reason for believing it to be affected in the remaining eleven,—we are, I think, justified in concluding that of the two diseases the affection of the endocardium is more closely associated with the development of nervous phenomena in acute rheumatism than is affection of the pericardium. Such conclusion naturally leads to the supposition that the cardiac murmurs, so frequently heard in cases of chorea unassociated with rheumatism, may also be dependent on some organic disease of the interior of the heart, "an insidious endocarditis affecting the mitral valves,"* and that such a morbid condition may have an important share in the production of the choreic phenomena. The mode in which such affection of the endocardium can bring about the nervous symptoms involves inquiries too lengthened for the present communication: yet it may be observed that there

No.	Sex.	Age.	Severity of Rheumatism, if present.	Nature of the Nervous Affection.	Date of commencement of Nervous Symptoms.	Previous Affection.	Affection of Heart.	Relation in point of time between commencement of Nervous and Cardiac Symptoms.	Results.	Remarks.	Authority and Reference.
1	F.	16	No rheumatism.	Delirium; chorea.	Chorea about 3d week; delirium earlier.	None noted.	Pericarditis (idiopathic).	Cardiac symptoms preceded the chorea.	Temporary recovery; subsequent death.	After death were found effects of pericarditis; lungs indurated; other viscera healthy; condition of endocardium not named.	Abercrombie, Trans. of the Med. Chir. Soc. of Edinburgh, vol. i. 1831, quoted by Dr. Burrows.
2	M.	17	Slight.	Chorea (very violent); delirium.	6th day after commencement of rheumatism, which had subsided.	Do.	Pericarditis; Endocarditis.	Unknown.	Death in 3 weeks.	Lymph in pericardium; vegetation on valves of left side of heart; brain healthy.	Dr. Bright, (Med.-Chir. Trans. vol. xiii.), quoted by Dr. Burrows.
3	F.	27	Severity not stated.	Delirium, with jactitation.	3d week of rheumatism.	Do.	Pericarditis.	Almost coincident.	Recovery.	Endocardium not named, but probably not affected.	Dr. Macleod, (on Rheumatism, &c.), quoted by Dr. Burrows.
4	F.	16	Moderate.	Chorea; delirium.	Not clear.	Do.	None detected.	—	Do.	Not clear that the heart was unaffected.	Dr. Burrows, (loc. cit. p. 196).
5	F.	14	Do.	Chorea.	3d week.	Chorea when 7 yrs old.	Systolic murmur at apex (endocarditis).	Both present on admission.	Do.	No previous rheumatism.	Dr. Ormerod, (MS. notes)*
6	F.	14	Do.	Chorea (slight).	3d week. (?)	None noted.	Double cardiac murmur.	Cardiac murmurs on admission; chorea 10 days afterwards.	Do.	Not clear whether pericarditis existed with the endocarditis. Sister to No. 19.	Do.

7	F.	14	Do.	Chorea (severe).	Do. (?)	Chorea. 18 months before.	Endocardial murmur.	No note of auscultation till 11 days after chorea.	Death (3 weeks after chorea).	Pericardium healthy; beads on aortic and mitral valves; brain and spinal cord congested. Never menstruated; anteversion of uterus.	Dr. Ormerod.
8	M.	10	Do.	Chorea.	See Remarks.	Chorea, unassociated with rheumatism, 4 years previously.	Recent endocarditis; recent and old pericarditis.	Both present on admission; (see "Remarks")	Do. (3 weeks after chorea).	A year before had rheumatism, with pain in heart and "inflammation of lungs," 4 weeks ago, pain in chest, followed in one week by chorea. Old pericardial adhesion; also soft lymph. Recent granules on tricuspid, mitral, and aortic valves; brain and spinal cord quite healthy.	Do.
9	M.	16	Severe.	Chorea (severe); delirium; convulsions.	10th day of rheumatism.	None noted.	Pericarditis; endocarditis.	Pericarditis on admission, 3 days before chorea began.	Death (7th day of chorea; 17th of rheumatism).	Recent lymph in pericardium; fibrinous deposit on mitral and aortic valves.	Do.
10	M.	14	Severity not stated.	Chorea.	On convalescence from rheumatism.	Chorea twice before.	Not noted.	—	Recovery.	At 8 years old had rheumatism; 4 months afterwards had chorea; in another year chorea again.	Dr. Todd, (Med. Gaz. N.S. vol. viii. p. 664).
11	F.	19	Moderate.	Do.	6th day of rheumatism.	Chorea 18 months previously.	Pericarditis.	Not noted.	Death.	Died after 4 days of chorea and 10 from commencement of attack; adherent pericardium.	Dr. Pritchard, (London Medical Repository, vol. xxi. p. 2).

* I have to thank my friend Dr. Ormerod for permission to analyse his valuable notes of this and the four following cases.

No.	Sex.	Age.	Severity of Rheumatism, if present.	Nature of the Nervous Affection.	Date of commencement of Nervous Symptoms.	Previous Nervous Affection.	Affection of Heart.	Relation in point of time between commencement of Nervous and Cardiac Symptoms.	Results.	Remarks.	Authority and Reference.
12	F.	15	Ordinary.	Chorea.	On decline of rheumatism.	Chorea when 12½ years old.	Endocarditis.	Endocardial murmur at 3d week of rheumatism; chorea later.	Recovery.	Sister had chorea; brother had rheumatism and pericarditis, without chorea.	Dr. Begbie, (Monthly Jour. of Med. 1847).
13	M.	13	Do.	Chorea (slight).	During or after rheumatism.	None noted.	None.	—	Do.	Brother to next case; had rheumatism before.	Do. (loc. cit. p. 746).
14	M.	14?	Do.	Chorea.	Do.	Do.	Endocarditis.	About coincident.	Death.	Died after chorea of several months' duration. Several previous attacks of rheumatism; heart healthy till last attack; diseased aortic valves after death.	Do.
15	M.	18	Severe.	Do.	On decline of rheumatism.	Do.	Do.	Not clear.	Recovery.	Slight but protracted chorea on convalescence from rheumatism.	Dr. Babington, (Guy's Hosp. Rep. vol. vi. 1841, p. 419).
16	F.	15	Ordinary.	Chorea (slight).	24th day of rheumatism.	Do.	Endocarditis; pericarditis.	Chorea subsequent to cardiac affections.	Do.	Chorea in left arm only, of short duration.	Do.
17	F.	16	Severe.	Chorea (moderate).	On decline of rheumatism. (?)	Hysterical.	Do.	Do.	Do.	Catamenia regular; began to menstruate at 13; the chorea began to subside on appearance of catamenia. Had rheumatism before.	Do.

	18	F.	15	None.	Chorea.	See Remarks.	None noted.	Pericarditis.	Uncertain.	Death.	Chorea for 6 weeks. Seemed to be getting well, when suddenly ensued convulsions, dyspnoea, and death in a few hours. Abundant old and recent lymph found in pericardium. Mitral valve somewhat thickened.	Do.
	19	F.	20	Very slight.	Chorea (severe).	7th day of illness.	Do.	Pericarditis; endocarditis; fatty discase.	Both present when first seen.	Do.	Sister to No. 6. Catamenia ceased at commencement of attack.	Dr. Kirkes, (Case 1, narrated) M. A. Burke.
	20	F.	13	Ordinary.	Chorea (slight).	16th day of rheumatism, which had almost subsided.	Do.	Pericarditis; endocarditis.	Chorea subsequent to cardiac affection.	Temporary recovery; subsequent death.	See particulars of case.	Do. Case 2—Ann Holt.
	21	F.	14	Severe.	Chorea.	Before the rheumatism.	Several attacks of chorea.	None. (?)	See "Remarks."	Recovery.	Three years later had chorea again, independent of rheumatism; at that time catamenia regular, and heart-sounds healthy.	Do. Case 5—Elizabeth Lark.
	22	F.	11	Ordinary.	Do.	Do.	Do.	Pericarditis; endocarditis.	Nervous affection preceded cardiac.	Do.	Two years afterwards had rheumatism and pericarditis without chorea.	Do. Case 3—Eliza Blenning.

No.	Sex.	Age.	Severity of Rheumatism, if present.	Nature of Nervous Affection.	Date of commencement of Nervous Symptoms.	Previous Nervous Affection.	Affection of Heart.	Relation in point of time between commencement of Nervous and Cardiac symptoms.	Results.	Remarks.	Authority and Reference.
23	M.	14	Severe.	Chorea.	During the rheumatism.	None noted.	None. (?)	See notes of case.	Recovery.	Ten years afterwards had another attack of rheumatism; on subsidence of which, severe chorea ensued, unaccompanied with signs of cardiac disease; a few months afterwards another attack, with endocarditis. First men-trusted during this attack; subject to chorea afterwards. Nothing detected after death but granules on mitral valve.	Dr. Kirkos. Case 4—William Harvey.
24	F.	15	Ordinary.	Do.	Do.	Repeated attacks of chorea.	Do.	—	Do.	First men-trusted during this attack; subject to chorea afterwards.	Do. Case 6—Maria Potter.
25	F.	17	None.	Do.	—	None.	Endocarditis.	—	Death.	Nothing detected after death but granules on mitral valve.	Do. Case 7—Ellas Fanchild.
26	M.	16	Ordinary.	Chorea (very severe).	On subsidence (3d week) of rheumatism.	None noted.	Do.	Uncertain.	Recovery.	His father, mother, and sister had shown evidences of insanity. It was so impossible to attack him during the long continuance of the violent chorea, that pericarditis might easily have existed and been overlooked.	Do. William Hobbs.
27	M.	10	Do.	Chorea.	On subsidence (5th week) of rheumatism.	Do.	Endocarditis; pericarditis.	Both existed when first seen, but appeared to have commenced almost coincidently.	Do.	—	Do. John Gilbert.

28	F.	17	Severity not stated.	Do.	In course of rheumatism.	Do.	Endocarditis.	—	Do.	"Bruit, at first audible below the mamma, disappeared under treatment."	Dr. Hughes, (Guy's Hosp. Rep. vol. iv.) Case 10.

33	F.	15	Do.	Do.	In course of rheumatism.	Do.	Pericarditis.	—	Do.	Endocardium not named.	Do. Case 98.
34	M.	18	Do.	Do.	Do.	Do.	—	—	Do.	"Heart permanently diseased."	Do. Case 99.
35	F.	15	Ordinary.	Do.	Before rheumatic or cardiac affection.	—	Endocarditis.	Chorea for 4 months; then rheumatism; then endocarditis.	Do.	Heart not named.	Do. Page 376.
36	F.	16	Do.	Do.	See "Remarks."	Do.	Pericarditis; endocarditis.	Almost coincident.	Death.	Rheumatism subsided first, then chorea, then the endocardial murmur. Only menstruated once, 5 months previously. A month before had left the hospital well from an attack of rheumatism, pericarditis, and chorea; returned with dyspnoea, cardiac pain, and general distress. In 17 days after readmission, pericardial friction, with chorea, which became most severe, and terminated fatally in 4 days. Solid lymph of various dates in pericardium; vegetations on aortic and mitral valves; firm coagula in each ventricle.	Do.

are reasons for believing that the efficient cause is in some way closely connected with that condition of the endocardium, or of the blood, or of both, which leads to the deposition of the fibrinous granules on the margins of the valves of the heart.*

Whatever may be the immediate exciting cause which calls the nervous phenomena into existence, there appears to be sufficient reason for believing that in most of the cases in which such phenomena arise there pre-exists a peculiar proneness to the development of nervous disorders, and that the rheumatic or cardiac affection occurring in persons possessed of such an evidently irritable nervous system, gives rise to symptoms which, in persons less predisposed to nervous affections, would probably not be developed. This opinion seems to suggest itself from a further analysis of the thirty-six cases I have tabulated, for such analysis demonstrates three important points:—1st, that the chorea is much more common (as has been often observed before) in females, in whom the nervous system is peculiarly prone to disorder, than in males, in whom this proneness does not exist; thus of the thirty-six cases two-thirds (twenty-four) occurred in females, one-third (twelve) in males. 2dly, that a large majority of the cases occurred at that period of life in which there naturally exists, especially in females, a peculiar tendency to nervous affections,—namely, the period of puberty, or of the first onset of the menstrual functions. Thus, on examining the ages of the several cases, we find that among the females the chorea occurred in one at 11 years old, in two at 13, in five at 14, in six at 15, in four at 16, in two at 17, in two at 19, in one at 20, and in one at 27. Out of the twenty-four females, therefore, no less than seventeen were between the ages of 13 and 17,—i. e., during the critical period

attending the development of the catamenial functions. A review of the male cases affords very similar results; for with the exception of one case, in a boy of 10, all the other cases occurred between the ages of 13 and 18.* 3dly, that in several of the cases there was distinct evidence of predisposition to nervous affections. Thus it is noted that no less than nine of the patients (5, 7, 8, 10, 11, 12, 21, 22, 24) had suffered from previous attacks of chorea, which, with one doubtful exception (10), were unassociated with rheumatism; and another case (17) occurred in a nervous hysterical girl. This number might probably have been greatly enlarged had attention been paid to this point in the history of the other cases; but unfortunately in nearly all of them there is no mention of the existence or non-existence of any previous nervous affection.

There are one or two other points exhibited by the cases, to which I may briefly allude before concluding this communication. On glancing at the fourth column, which relates to the severity of the rheumatic attack when present, it will be observed that of the thirty-three cases in which the chorea was more or less directly associated with rheumatism, the rheumatic attack is described as being

Severe in	cases.
Ordinary or moderate in 17	"
Slight in	2 "
Severity not stated in	9 "

It may be assumed that in the last nine cases, in which there is no record of its severity, the attack was either slight or ordinary. But even supposing these nine to have been severe, we still find that in more than half the number the rheumatic attack was moderate or of an ordinary kind, and that therefore the development of the nervous phenomena cannot be ascribed to the severity of the rheumatism. From the sixth column, again, we learn that in those cases in which the period of the commencement of the chorea is noted, the nervous symptoms usually

* As bearing on the comparative frequency with which the pericardium and endocardium are affected in chorea, I may also notice that the valves of the heart were affected in all six of the fatal cases of chorea tabulated by Dr. Hughes, in which the condition of this organ is named; while the pericardium was found inflamed in only three of them, and in no case without coincident affection of the valves. The affection of the valves in four of the cases consisted in the presence of granules of fibrine on the borders of one or more of the valves, while in the other two cases the mitral valve is described as being merely "opaque" and "thick."

* I need not go further into this part of the subject, since the same views in relation to chorea in general, though not to chorea in rheumatism, have been fully developed by Dr. Hughes in his valuable paper in Guy's Hospital Reports (vol. vi.), with which I did not become acquainted until after the substance of this communication was read before the Abernethian Society.

arose, not at the beginning or climax of the rheumatic attack, but on its subsidence. The ninth column, relating to the precedence of the cardiac or nervous symptoms, is occasionally incomplete, from the impossibility in many cases of obtaining the requisite information; but in most of the instances in which such information was procured, it will be seen that the cardiac affection preceded the development of the nervous phenomena.

Of the thirty-six cases here tabulated no less than eleven, almost one-third, terminated fatally. In all of these there was found some affection of the heart after death,—viz., pericarditis in 8, and endocarditis in 9. The brain and spinal cord, when stated to have been examined, as they were in at least five cases (2, 7, 8, 19, 25), presented no trace of inflammation, and nothing which seemed to bear particularly on the pathology of the disease. This is important in reference to the opinion which has been advanced, that the choreic symptoms are dependent on extension of the rheumatic inflammation to the fibrous membrane of the brain or spinal cord; for it shows that such symptoms may ensue and terminate fatally, without leaving any trace of inflammatory affection of the membranes or substance of the nervous centres, and fairly allows of the inference that in favourable cases also the nervous centres are equally free from inflammatory changes.

SUBMISSION TO AUTHORITY IN MEDICINE.

SPECULATIVE truth and the resulting practice lie within the domain of opinion, which is by nature free, and cannot be brought into bondage to any man, or any number of men. Moreover, it is not necessary that all questions should be settled and ended; it is necessary only that the truth should be known, and when every man has given his testimony faithfully he has done his whole duty; a step farther, and he is trespassing on the rights of others. Settling a question of opinion by authority is only in fact unsettling a great principle, by arresting inquiry, and forbidding future experience to illustrate and modify the past. Science is not a despotism, and its real cultivators are all equally freemen; and their liberty is as essential to the progression of truth as it is to individual honour.—*American Journal of the Medical Sciences.*

ON THE RISE, PROGRESS, AND VARIOUS TERMINATIONS OF CHRONIC OVARIAN TUMORS.

By EDWARD JOHN TILT, M.D.

Senior Physician to the Paddington Free Dispensary for the Diseases of Women and Children, &c. &c.

[Continued from p. 962.]

HAVING described the effects of ovarian tumors on the unimpregnated womb, we shall now enter upon a subject of more practical importance, and investigate—

2ndly.—The effects of ovarian tumors on the impregnated womb.

When pregnancy coincides with the existence of an ovarian tumor, it has been known to determine abortion when there was still ample room for the development both of the pregnant womb and of the tumor; but this is of very rare occurrence: it has more frequently brought on premature labour or necessitated repeated punctures, as in Emery's case, who thought it necessary to tap a patient six times to prevent this occurrence. Generally speaking, however, the morbid and physiological tumors progress side by side until the full period of pregnancy, as in a case which has recently occurred, wherein after a woman was delivered of a full-born child, "A large house-pail of fluid" was taken from an ovarian cyst. Impeded respiration rendered it necessary to tap the patient, who died under the operation, but unfortunately the relations would not permit a post-mortem examination.

When, from the length of its pedicle, or from its mode of attachment, the tumor is situated by the side or above the enlarged womb, it neither impedes labour nor aggravates its phenomena.

Often a small or moderately-sized tumor, or a lobe of an irregular shape, prolapses into the recto-vaginal space before parturition has come on, or descends into this space towards the end of gestation, when nature is preparing for the delivery of the woman by a general relaxation of the soft parts of the pelvic cavity. Such cases have been described by Merriman, Denman, Ingleby, Madame Lachapelle, and others; and they often seriously complicate labour, unless, as we shall

see when we come to the treatment of these affections, there is a possibility of pushing up the tumor above the womb, in imitation of what in similar cases has often been effected by the sole powers of nature. In the following case, related by Madame Boivin, the tumor was displaced by a species of evolution. It suffered with impunity the irritation of one labour, but in that which followed the cyst inflamed and caused the patient's death by its rupture.

On the 31st July, 1831, says Madame Boivin, I visited Mrs. M—— early in the morning. She had been in labour some hours. On examination, I found a tumor filling the vagina, which seemed to grow from its upper and posterior surface. It seemed to be a solid and fleshy mass, and its magnitude gave me great apprehensions for the result of the labour. I had attended the patient in former labours, when she had always done well, and no such obstruction had ever, till then, been met with. The pains were violent, and the head of the child made slow progress in front of the tumor. After more violent and protracted efforts, the child was born in the evening of the same day. Immediately after delivery I examined the vagina, but the tumor had disappeared, and the patient got well as usual without anything occurring worthy of notice.

May 9, 1834.—Again attended Mrs. M—— in labour. On examining, I found the tumor as before, and I was as much at a loss as ever to determine its nature. The labour was accomplished with much less difficulty than on the former occasion, and again the tumor disappeared. There was some hæmorrhage, but the placenta was expelled by pains; the uterus seemed to be well contracted, and the hæmorrhage ceased. Her pulse was quick, and she complained of unusually severe after-pains, especially in the back. In half an hour I was again called to her. She had now the appearance of sinking from hæmorrhage, but there was no discharge. The pain in the back was agonizing: opiates failed to produce relief; the exhaustion kept increasing, and she died in about two hours. Next day we examined the body, which had a very exsanguine appearance. The uterus was contracted and without blood in its cavity, nor was there any substance in the vagina. A fleshy-looking tumor

was seen rising from the left side of the pelvis, which on being cut into was found to contain about a pint and a half of pus, mixed with a considerable quantity of hair appearing like tow. The hair did not seem to be attached to the sides of the bag which held it, but to be loose in the cavity. This tumor I believe to have been the left ovary, and the same which, on the occasion of the two labours, had been found in the pelvis, protruding the vagina before it and producing the impediment to delivery.

From this narrative, it appears that the ovary was in each labour forced down by the child's head, and, excepting on the occasion of the last delivery, was drawn up again into the abdomen immediately afterwards.

The following interesting and unpublished case of mismanaged labour occurred in the practice of my friend Mr. Wollaston, whose judicious interference could not ward off a fatal termination.

A woman, 35 years of age, had become pregnant of her first child, and was taken with symptoms of labour at the eighth month. She was unmarried, and had taken several drastic purgatives to produce abortion at an early period of gestation, but not latterly. Prior to labour, she had frequently complained of severe pain on the right side of the abdomen, near the crista ili. After the labour had begun, the pains were inconsiderable, but continued at intervals for seven or eight days, when the membranes burst, and the liquor amnii escaped gradually, and continued doing so during the succeeding days; mixed with purulent secretion of a very offensive odour. The pains for nearly twenty-four hours had become nearly suspended; they were restored apparently by the use of the ergot of rye and nourishment, and progressively advanced the head into the pelvis. Again there was a complete remission of uterine power; the woman was greatly exhausted. On the 4th day after the membranes had ruptured, her medical attendant requested my assistance. I found the head of the child firmly fixed quite low in the pelvis; the os uteri was sufficiently dilated, but she had no expulsive pains whatever. I immediately applied the forceps, and delivered her without difficulty. The placenta soon followed quite entire, and the

uterus appeared well contracted, and very little hæmorrhage occurred. The child was dead, and seemed to have been so for perhaps three or four days. During the first twenty-four hours after her delivery she seemed doing well, was in tolerably good spirits, and expected soon to get well. On the second day she was restless, had some slight fever, and the abdomen became flatulent and swelled, yet *without any pain on pressure*. The milk was never secreted; the lochia were scanty, but mixed with a good deal of most foetid pus. The abdomen was carefully fomented, Dover's powder and antimony given, and her strength supported with beef-tea. In three or four days she seemed to mend, when she gradually sunk from exhaustion on the fourteenth day after her delivery. During the last ten days her pulse was extremely feeble. She complained of *no pain*, her tongue was slightly furred, and she had no acute symptoms of any kind.

Post-mortem examination.—The serous membrane of the intestines and the abdomen was *full*, and indicated no inflammation. A large ovarian cyst on the right side was the first thing to attract our attention: it contained about a quart of sero-purulent fluid; its inner membrane was very vascular and studded over with numerous depositions of lymph: the body of the right ovary was shrunk up; the uterus was flaccid; the mucous membrane intensely inflamed and disorganised; a collection of pus filled its cavity; the cervix and os uteri were black and almost sphacelated; the vagina also was greatly congested; the left ovary contained several small cysts, one of about the size of a bean, containing secretion similar to that of the large cyst of the right ovary.

REMARKS.—Connecting the symptoms accompanying the labour and the subsequent period with the appearances after death, there can be no doubt, I think, that the inflammation and supuration of the uterus accompanied the labour and preceded its termination. Suppuration exhausted the powers of the patient, and uterine contraction consequently ceased, and rendered her incompetent to give birth to the child, and the long period of labour—nearly four days—so aggravated the inflammation of the uterine cavity as to lead to a fatal result.

Mr. Wollaston thinks that the disease originated in the ovarian cyst, was propagated by the Fallopian tubes, and thus invaded the womb; but we cannot admit this explanation, for the cyst was a perfectly closed sac unconnected with the corresponding Fallopian tube. The protracted labour was sufficient to explain the lesions which were found, and which were quite serious enough to cause an abundant suppuration. Protracted labour brought on inflammation of the cyst, as it did that of the womb.

Thus the womb, when about to accomplish its important function, may displace a tumor which impedes the performance of that function. When it cannot do so, it frequently bursts the tumor, so as to evacuate its contents through the vagina, and to allow parturition to proceed in safety; and, when we consider what an enormous amount of pressure nature employs to produce delivery, we need not wonder that it often crushes in this manner an ovarian cyst. This occurred in a case related by Dr. Ashwell. The labour was obstructed by a tumor which burst into the vagina, and discharged a dark, offensive fluid. Delivery was then shortly effected, but death took place on the second day. On examination post-mortem, a large cyst was discovered growing from the left ovary, the vagina being ulcerated and gangrenous at the part where it communicated with the cyst (Guy's Hosp. Rep. No. 2). A case is also reported by Dr. Langley of an ovarian tumor which burst during labour, and was attended by the escape of several gallons of serous fluid (No. CXL. vol. vi. of Lond. Med. and Surg. Journ., Oct. 4, 1834, p. 319).

Mr. Brown has lately published a case which illustrates this termination of ovarian dropsy. It is as follows:—"I was called to see a lady pregnant with her second child. I found her ill and weak, complaining of the enormous size of her abdomen, and satisfied in her own mind that she should have twins. At the proper time labour came on, and the child was born without difficulty: but on placing my hand externally to grasp the uterus, I found I could not feel it, for the pelvic cavity was filled by a soft, elastic tumor, and the uterus had ascended out of the pelvic cavity, and was above this tumor. In introducing my hand into the vagina,

and endeavouring to reach the uterus to remove the placenta, and pressing my other hand over the uterus, I had the pleasure to feel the tumor, which I felt was an ovarian cyst, suddenly rupture, and discharge its clear amber coloured fluid down the side of my arm. On a subsequent confinement not a vestige of this tumor could be felt."

An ovarian cyst may produce scarcely any impediment to delivery, and yet the portion of the sac which has entered the septum may inflame, discharge its contents, and the patient recover. Thus Dr. Davis saw a tumor in the left iliac region, complicating but not impeding labour, produce dangerous symptoms, and burst in the vagina on the 27th day after delivery. The tumor disappeared, and the patient recovered. Whether the disease was ovarian or uterine could not be positively determined, but it was most likely the first.

The bursting of the cyst, and effusion of its contents into the peritoneal cavity, is a third termination of ovarian cysts, and we shall soon show that the accident is attended by much less danger than has been hitherto supposed, provided the contents be of a fluid and albuminous nature. Dr. Ingleby had noticed this termination during pregnancy. Mr. Headland (*Lancet*, June 22, 1844) relates a case, and Dr. Peddie (*Medical Times*, Feb. 22, 1844) mentions that a woman, in whom he clearly detected an ovarian tumor about the size of a child's head, became pregnant, and after delivery no trace of it could be found. It is therefore fair to conclude that it burst during delivery; and, as it did not re-appear, that it was effectually cured.

There is a fourth termination of an ovarian tumor—the expulsion of the whole tumor through the vagina. There is, as far as we are aware, but one recorded instance of this natural operation of extirpation of the ovary, and it has been published lately by Mr. Rankin, of Carlisle, in the *Edinburgh Monthly Journal* (July 1850).

Mrs. G——, 27 years of age, was the mother of five children. The first two labours were natural; but after a difficult labour, from an unascertained cause, she again became pregnant. A large tumor, occupying the cavity of the pelvis, interrupted the efforts of Nature at the next birth, and delivery with the

crotchet was with difficulty accomplished. The patient again became pregnant; and, as the tumor was now of greater size, delivery by the natural passage was considered impossible. Delivery was effected, however, by turning the child and forcing the tumor from its place in the pelvis upwards. Thirty-eight days subsequently a tumor was expelled from the body. It was a partially putrid mass, ten inches long, five broad, and weighing fourteen ounces, consisting of a dense, fibrous substance, fringed here and there with small cells, emptied of their contents. I examined the vagina (says Dr. Rankin), and detected an opening, small compared with the size of the diseased parts, which must have passed through it; yet, after contraction, it freely admitted two fingers. It was irregular in form; the parts around were indurated; and, with the aid of the speculum, they were found to be inflamed. The bulk from the tumor above the pelvis had entirely disappeared; but on pressure upon its former seat, and counter-pressure from within the vagina, there was still considerable fulness, which might arise from induration of the parts concerned in the recent separation and rejection of the morbid structure. If we listen to the testimony of Dr. Selkirk, of Carlisle, in whose practice the case occurred, and who followed it throughout, we must undoubtedly admit that the tumor was fibrous and ovarian:—

"I am convinced (says Dr. Selkirk—*Lancet*, Oct. 1850) for the following reasons—be the tumor ovarian or not—it was not intra-uterine. The tumor occupied, during the intervals of impregnation, the right iliac fossa, as was evident to the eye, and palpable to the touch; and, on internal examinations, it always pointed in the same direction. I remember well that, during the first stage of labour, in her confinement in 1846, which was protracted from what I at that time deemed an unusual thickening of the posterior portion of the cervix uteri, or the hand partially introduced in order to arrive at a more satisfactory knowledge of the presenting part, the fingers passed beyond the indurated point, and into the uterus. Again, at her labour in 1848, in which the perforator and crotchet became necessary, being obliged to remove the placenta by the hand, the uterus, gliding down by the margin of the tumor,

contracted ball-like, quite as low as usual, and to the left iliac fossa. Further, in her labour in February last, I again removed the placenta, the uterus contracting distinctly downwards by the margin of the tumor; and manipulation by the fingers externally detected the womb isolated from, and to the left side of the morbid growth. Now is it at all likely, admitting the tumor to be uterine, that the organ would contract so regularly, satisfactorily, and to its ordinary dimensions, around such a large, diseased mass? I opine not."

We have been careful in establishing the preceding facts, because the case is one of interest, and because it proves that we cannot as yet accord to the microscopical investigator, however eminent he may be, the right of deciding all pathological questions. The fibrous tumor was examined by Professor Goodsir, who said that it could be nothing else than a uterine fibrous tumor; and, influenced, no doubt, by so excellent an anatomist, a distinguished midwifery professor also considered the tumor to be uterine.

We have already shown that this cannot be admitted. Dr. Selkirk recognised its independent extra-uterine position at the labour previous to the one after which it was expelled. It was evidently torn from its pedicle by Mr. Rankin during the operation of turning; for we read (Edinburgh Monthly Journal, July 1850, p. 14):—"Very considerable force was necessary to bring the child into the pelvis. During the operation the tumor was gradually *forced up* from the cavity of the pelvis into that of the abdomen, and a sensation of *tearing was communicated to my hand, and rendered audible*, which led me to conclude that some fearful disaster was impending. This was soon found to be referable to the parts of the mother, for the child was born uninjured." The rent through which the tumor passed was seen by means of the speculum; and we may well admire the wonderful agency by which such a tumor was with impunity expelled from the peritoneal cavity of a patient thus almost miraculously cured of a usually fatal complaint; while the well-being of both mother and child shows that Mr. Rankin's conduct should be imitated in a similar case.

It appears that not only the vagina, but the uterus itself, has been perforated through the instrumentality of an ova-

rian tumor, which, by producing an obliquity of the uterus, effectually pushed the head of the child out of the axis of labour, bringing it to bear on the edge of the pelvis with sufficient force to cut through the walls of the uterus. Tumors of the fallopian tubes are less frequent than those of the ovary, so do they less frequently cause serious obstruction to parturition. We believe there is but one case on record when this occurred; it is given by Chambon de Boulage (Anciens Journal de Med.-Chir. et Phar.) The patient died, and the obstruction was found to have been caused by an irregularly-shaped, hard, and in part osseous, tumor. It is not surprising that this complication should be a frequent cause of mortality. Thus of the 31 cases given in Puchelt's valuable work

- 1 died without being delivered.
- 14 " soon after delivery.
- 3 " from other causes.
- 13 recovered.

—

31
Dr. Merriman states that out of his 18 cases

- 9 died.
- 3 recovered imperfectly.
- 6 " perfectly.

—

18
The danger in this complication of pregnancy to the children may be inferred from the fact, that out of Puchelt's 32 cases

Children.

- 21 died before delivery.
- 2 " after it.
- 7 born alive.
- 2 result not stated.

—

32
In Dr. Merriman's cases there were 16 still-born children.
4 born alive.

Even when not fatal to the child's life, the pressure of an ovarian tumor may produce a malformation of the skull in the fœtus, as in a case related by Mr. Langley (Lond. Med. Jour. vol. vi. 1844).

Effect of ovarian tumors on the bladder.—The bladder soon feels the pressure of an ovarian tumor, and it often affords the first indication of its slow

beginnings. It gives rise to a frequent want of passing water, which is the result of a nervous irritation, most distressing to the patient, long before the tumor has acquired a sufficient size to diminish the capacity of the bladder. At a later period of its growth, if the tumor cannot rise from the pelvic cavity, it may press on the urethra, and so impede the passage of the urine that the patient is obliged to bear forcibly backward in order to pass water. When the whole tumor is pelvic, or when a considerable portion of it is forced into the pelvis, it presses so forcibly on the urethra as to render impossible the flow of urine, and require catheterism. It has even necessitated the puncture of the cyst by the vagina, as in a case which occurred to Mr. Ogden (*LOND. MED. GAZ.* Jan. 1840).

When, however, the tumor completely, or even partially, leaves the pelvic cavity, all signs of vesical disturbance cease, and although the bladder may be displaced (as in a case related by Portal), or drawn up, pushed on one side, and diminished in size, still it, generally speaking, adapts itself with wonderful facility to the emergency. It is only in some cases, when a tumor is firmly lodged in the vesico-uterine cleft, that, as it increases, it presses against the bladder, and may thus divide its area into two cavities, both containing urine. This presents one of the most difficult problems of diagnosis; for when the attendant introduces the sound he only penetrates into the anterior chamber of the bladder, he only withdraws a small quantity of urine, which but little diminishes the size of the tumor, because the posterior chamber remains full. In another work we have given a case of this description wherein the urine is forcibly retained, and still continues to dribble out (*On Diseases of Menstruation and Ovarian Inflammation*, p. 30). In rare instances adhesions take place between the cyst and the bladder, and after a perforation of the walls of both cavities the contents of the cyst pass into the bladder, and may be thus ejected.

The passage of pus from an abscess into the bladder has been seen to bring on chronic cystitis by Emery, Louis (the elder), and Lisfranc, and Dr. H. Johnson (*Med.-Chir. Review*, 1836), saw it bring on frequent desire to pass water, dysuria, and hematuria. Generally,

however, the passage of pus into and through the bladder has no injurious effects. Cases of this description have been reported by Cæsar Hawkins, Dr. Gordon of Aberdeen; and abroad by Menière, Dancé, Martin, Madame Boivin, and in two instances by Marshal de Calvi. Out of these nine cases eight recovered. Besides, it is not pus but a fluid, which in general may be less irritating than pus, we say in general, for we have already mentioned that a distinguished surgeon of Brussels extracted from the bladder of a patient a stone having for its nucleus a tooth, which most probably came from an ovarian cyst. Although the following case occurred in the male, it so well exemplifies the innocuity of some of the contents of hydatid tumors when placed in contact with the urinary surface, and is so interesting for other reasons, that we shall give it as stated by Dr. Bright, in one of his valuable papers in the *Guy's Hospital Reports*.

W. Skingley, aged 54, was admitted into Guy's Hospital labouring under serous effusion, with dyspnoea and coagulable urine. He died, and on examining the body a tumor was found, about the size of a large orange, between the bladder and rectum, pushing the bladder forwards. The tumor was hydatid. It had given rise to no retention of urine, or at least none was noticed. The patient, who had been labouring under other disease, complained of the difficulty he had in retaining his water; and, when the examination was made, it appeared that the urine was continually passing away, and that a tumor bearing all the characteristics of a distended bladder presented itself at the pubic region. A catheter was introduced, and a few drops of perfectly healthy urine drawn off without producing any diminution in the bulk of the tumor, as it was still supposed that the urine was retained. More than one medical man attempted to draw it off, and at length the catheter became obstructed by the passing of some hydatids. A sucking-pump was applied to the catheter, and thus a considerable quantity of the "debris" of hydatids was removed. The patient died of his principal complaint, and a large hydatid tumor was found to fill the pelvic region, attached to the posterior part of the fundus of the bladder, pressing so much forward as to prevent the bladder from being filled with urine,

and causing its constant escape. The catheter had not passed through the bladder to reach the cyst, but, on the contrary, had passed by an opening from the urethra behind the bladder.

Dr. O. Heming relates a case in point in his translations of Mme Boivin and Dugés' work:—"The bladder being opened by ulceration, it allowed for a long time hair to pass with the urine; at last a body was abstracted from the bladder as large as a hen's egg, presenting at one of its extremities a shred of skin containing hair and bone, in which was a kind of tooth resembling a small molar. The communication of the cyst with the bladder was ascertained by the finger passed into the urethra. The person recovered."

The most remarkable instance of this favourable termination was published by my friend Dr. Bennett of Edinburgh (*Monthly Jour. of Med. Sci.* Feb. 1849), and deserves to be given in full.

Case of Spontaneous Cure of Ovarian Dropsy, by means of an Ulcerative Opening of the Cyst into the Bladder.

CASE.—Anne Pyper, a servant, aged 25, was admitted into the female clinical ward of the Royal Infirmary, Nov. 8, 1848. She had been delivered fourteen days previously of a male child in the Maternity Hospital; and, on inquiry, I found that the labour was a natural one, and presented nothing unusual. On the birth of the child, however, the abdomen still continued enlarged; and at first led to the suspicion that another fetus remained in the uterus. After a time the true nature of the case was rendered manifest, and a large swelling was detected, which was moveable to a certain extent, and presented all the characters of an encysted tumor of the left ovary.

When I first examined her in the Infirmary, I found the abdomen swollen to about the size of a woman's during the sixth or seventh month of pregnancy. The tumor extended from the epigastrium to the pubes, but bulged considerably towards the left side. Its surface was irregular; and two large nodules, each the size of a cocoa-nut, existed about its centre. It was tense and firm to the feel, somewhat elastic, but no fluctuation could be detected. The tumor was firmly fixed, and the seat of constant pain, especially in the

left lumbar region, which was increased by pressure, by lying on the right side or on assuming the erect posture. The urine was of a slight yellow colour, and presented its normal characters. The digestive, respiratory, circulatory, nervous, and integumentary organs appeared to be healthy. She had observed the tumor seven months before her delivery; and it has gone on gradually increasing, and been somewhat painful from the first. *Eight leeches were ordered to the most painful part of the abdomen.*

For four days the patient remained in the same condition, the local pain, however, having been relieved by the leeches. On Nov. 12th, my attention was directed to the urine, which now presented a copious white deposit, occupying two-fifths of the jar, while the supernatant portion was of a light amber colour, and unusually viscid. The deposit was determined by the microscope to consist of pus, mingled with a few compound granular corpuscles. The clear portion was strongly coagulable by heat and nitric acid.

At first I imagined that the cyst had burst into the vagina, but the patient and nurse assured me that there was no discharge between the intervals of micturition, and that all the fluid came from the bladder.

The urine presented the same characters during the next three days; the amount discharged during the twenty-four hours being about three pints. On the 15th, I observed that the tumor had somewhat diminished in size, its hardness and tensility had disappeared, and distinct fluctuation was perceptible in it. *A broad flannel roller was ordered to be firmly applied round the abdomen, and compression made by means of pasteboard, previously soaked and modelled to the abdominal surface.*

From this time the abdomen rapidly diminished in volume, while the amount of purulent viscid fluid discharged from the bladder varied from three to five pints in the twenty-four hours. The appetite and general health continued good; and she was ordered nutritious diet, with four ounces of wine daily. On the 23rd, the amount of pus contained in the urine was greatly lessened, and the clear portion presented a slight haziness on the addition of nitric acid. On the 27th the abdomen had regained its natural size, although a dense mass, evidently the collapsed ovarian sac,

could readily be distinguished, occupying the left iliac and hypochondriac regions. The urine now also was natural in quantity, and presented only a slight sediment, consisting, as shown by the microscope, of some crystals of oxalate of lime, and a few pus globules.

From this period she may be said to have recovered. She suffered occasionally from uneasy feelings on the left side, sometimes amounting to pain, which were relieved by the application of four leeches, followed by a small blister. One of the leech bites ulcerated superficially, but soon healed up. She was dismissed on the 18th of December, expressing herself as being well in every respect, having been sitting up and running about the ward for the fortnight previous. The indurated mass in the left iliac region was greatly diminished in size, but still very perceptible to the feel, though not to the eye."

Effects of Ovarian Tumors on the Kidneys.—The kidneys are very rarely implicated. Burns is the only author, with whom we are acquainted, who mentions their partial atrophy as the result of the pressure of an ovarian tumor, and we have never met with a similar appearance. It is not unreasonable to suppose, with the same author, that when the tumor occupies the entire abdominal cavity, suppression of urine may arise from the pressure of the cyst upon the kidneys: diuretics fail to increase the quantity of urine, though this may be effected by paracentesis. This assertion is well exemplified by a case given by Burns, of Madame de Rosney, "who in the space of four years was tapped twenty-eight times." For seven days after each puncture she made water freely, and in sufficient quantity; the appetite was good, and all the functions well performed; but in proportion as the tumor increased the urine, in spite of diuretics, diminished, and at last came only by drops.

This is the place to mention an interesting case, of a large monocular ovarian cyst, which we saw in consultation with Messrs. Wetherfield and Duncan, and in which the fatal termination was no doubt accelerated by extensive disease of the kidneys. Several weeks before the patient's death the urine was abundant, purulent, and very offensive, and it was a question with us whether there was not some com-

munication established between the bladder and the cyst, but on opening the body the cyst was found to be entire, without any trace of inflammation, containing five or six pints of albuminous fluid of a straw colour, while the right kidney was three times its natural size, and in a state of decomposition. The left kidney was tolerably healthy, and the bladder and urethra perfectly so. If this disease of the kidney was not caused by this large ovarian cyst, it no doubt increased it.

[To be continued.]

DECADENCE OF THE PROFESSION IN THE UNITED STATES.

It is most cheerfully conceded that in those schools which, twenty years ago, sent out their three or four hundred graduates annually, the graduates of every subsequent year have progressively improved, partly in consequence of their previous education being better, and partly because the medical courses have been perfected. But what shall we say of a large portion of the six or eight hundred annual graduates who are now poured out by more recently established institutions? We are persuaded that in average attainments they do not reach the standard of graduates of twenty years since; and, what is worse, that after entering the profession they are much more apt to remain stationary. For while in the olden time the student was at least impressed with the dignity, excellence, and sacredness of his calling, the class of modern students to which we have alluded become physicians with such motives as ought to lead them to be blacksmiths or carpenters, or members of some fraternity in which they might be really useful to mankind. But they take up physic as a trade, they are taught by traders in diplomas, and they practise in the true spirit of tradesmen. And as for improvement, they vote all discoveries a humbug, and study a bore. Yet these persons, physicians in name, and by virtue of a parchment title, claim and assert an equality of rank with the well-educated, the high-minded, the studious, and progressive members of the profession. They form a part of the same body politic, and by their character and conduct determine its estimation in the world. Twenty years ago nearly all graduates of medical schools were sure to possess a respectable degree of knowledge and skill; but now, although the graduates of a certain number of schools have higher attainments than ever, the remainder occupy the very lowest point in the scale, which begins at the zero of ignorance and ends at the climax of wisdom.—*American Journal of the Medical Sciences.*

CASE OF
REDUCTION EN MASSE.

By J. WEIR D. BROWN, M.R.C.S.E.
Demonstrator of Anatomy in the School of the
London Hospital.

I FORWARD for publication in your valuable journal the following interesting case:—

Lewis Lyon, a broker, aged 72 years, was admitted into the London Hospital on the 3rd day of October, 1850, under the care of Mr. Luke. The patient stated that he had, during the last seventeen years, occasionally suffered much from a reducible inguinal hernia, which, whenever the truss that he wore was for a short time removed, came down. On those occasions he said that he had always succeeded in returning the hernia himself, but that on the 29th ult., having taken off his truss, the hernia descended and speedily became larger and more painful than usual. He at this time grasped the swelling with both of his hands, pushing it violently upwards, and in this way succeeded in returning the greater part of it into the abdomen; but, from the force he used, his fingers, he said, became benumbed, and that he was on that account obliged to desist, and to send for a surgeon, who completed the reduction. The pain in the belly, however, soon after this became more severe, and afterwards, during that day, he had two scanty stools. The pain during the succeeding night increased in severity, and early on the following morning retching and vomiting took place, which, he said, had been constant ever since.

On admission there was a tumor occupying the right inguinal canal, which receded into the abdomen when the slightest pressure was applied to it with the finger, and the surface became like that on the opposite side; the tumor again appeared on coughing. It was observed that the ring was large, and readily admitted the finger, with the fold of skin which was pushed before it. The spermatic cord was clear, and unobscured by any overlying sac. When reduced within the abdomen, there could be felt a fulness above the inner ring, attended by pain on pressure. Thinking it probable from these circum-

stances that the hernia had been reduced with its contents still in a state of strangulation, Mr. Luke, without delay, determined to perform an operation of exploration.

The patient being placed on the table, Mr. Luke made an incision over the inguinal canal by pinching up and transfixing with a straight bistoury a fold of integuments, after which the parts intervening between the integuments and the tumor which had reappeared were carefully divided, and the sac opened, when its contents were brought into view. They were found to consist of discoloured intestine, lying nearly wholly within the parietes of the abdomen, and encircled by a stricture formed by the neck of the sac, the stricture being about one and a half or two inches distant from the internal ring. The sac was drawn partly from the abdomen for the purpose of facilitating the division of the stricture. When the stricture was divided, the hernial contents were replaced within the general peritoneal cavity, and the wound closed with sutures, &c.

Eight hours after the operation the patient had four copious stools; she then fell asleep, and passed a good night.

Oct. 4th.—The patient, this morning, is in rather a low state. He has had no vomiting since the operation, and says that he is free from pain. Ordered a pint of beef-tea, and eight ounces of wine during the day.

5th.—The dressings have to-day been taken off and the sutures removed. He complains of heat and pain, which, he says, extends from the wound to the bottom of the scrotum, and those parts are red and inflamed. The bowels have not been opened since the day before yesterday.—R. Ol. Ricini, \mathfrak{ss} . statim sumend' and an evaporating lotion to be applied to the part.

6th.—The patient appears to be weaker this morning. The redness, heat, and pain in the scrotum, &c., are greater than yesterday. Bowels have not yet been opened. Another half ounce of castor oil to be immediately given. The inflamed parts to be covered with collodion, and two pints of porter to be taken during the day; the wine also to be continued.

7th.—The patient has passed a restless night on account of pain about the

scrotum and spermatic cord. Bowels have been opened by the castor oil. Colloction to be reapplied to the inflamed parts.

Vespere, 9 o'clock.—Nearly as in the morning; restless, and unable to sleep.—*℞* Aqua Pur. 3j.; Tr. Opii, ℥xx. Fiat haustus statim sumend.

8th.—Nearly as yesterday. The wine to be increased to twelve ounces, and the anodyne draught to be repeated at bed-time.

9th.—The pain in the parts more severe, and the swelling of the scrotum greater. Patient very low. Pulse slow and weak; stomach irritable; occasional slight singultus.—*℞* Infus. Gentian. Co., 3iss., Ammon. Carb. gr. v. Fiat haustus ter in die sumend. *℞* Morphiae Acet. gr. ss.; Confect. Aromat. gr. iv. Fiat pil. hora somni sumend.

10th.—A fluctuation being this morning perceptible, a puncture was made with a lancet, and a considerable quantity of matter removed. Bowels open.—Infus. Gentian. ut antea.

11th.—As yesterday.

12th.—Much better in every respect. Abscess discharging freely. Pulse stronger; appetite returning: a mutton chop to be taken for dinner.

13th.—As yesterday. Bowels confined.—*Ol. Ricini*, 3j.

18th.—The patient has been rapidly improving since last report. The swelling of the scrotum has diminished, and the wound in the groin is now entirely healed, and slight discharge still continues from the puncture that was made in the scrotum.

25th.—Doing well.

30th.—The patient since last report has been out of bed for three or four hours every day, and is now quite convalescent. The wine to be continued, with nourishing diet.

Nov. 11th.—Discharged cured.

REMARKS.—With reference to the above case, it may be observed, that the result bears evidence of the value of the means of diagnosis adopted in it, and of the truthfulness of the observations which Mr. Luke has made in his paper upon this subject, published in the xxvi. volume of the Transactions of the Royal Medical and Chirurgical Society. It appears to be important that these means of diagnosis should be well understood; because, upon their admitted

accuracy, depends the promptitude with which surgeons may be disposed to have recourse to early relief; and it is to be regretted that so few cases of this description, relieved by operation, have been published, as there is reason to believe that such cases are far more common than has generally been acknowledged by authorities.

I learn that the above is the ninth case which has come under Mr. Luke's observation, and the sixth on which he has operated, the results being, that only two patients died,—one from lesion of the intestine, mortification having taken place previous to the operation, and the other seven days after the operation, from erysipelas attacking the wound,—the symptoms of obstruction having entirely ceased, and the bowels having recovered their perfect function. If so many cases of this kind have occurred in the practice of one surgeon, it is but fair to conclude that they may have taken place in a somewhat similar proportion in the practice of other surgeons, and yet we do not hear of their having been relieved by operation. Is, then, the inference here drawn respecting the frequency of such cases, correct, or is it not? If it be correct, and operations have not been performed on account of the obscurity by which such cases are surrounded, the publication of the above, may, in future, be useful in assisting the diagnosis, and in keeping attention alive to the subject of strangulated hernia reduced *en masse*.

London Hospital, Nov. 25th, 1850.

THE TREATMENT OF INTERMITTENT FEVER
BY FERROCYANIDE OF POTASSIUM AND
UREA.

[We substitute the following for a paragraph on the same subject which appeared at page 1014 of our last number.]

M. Lemaître, of the Hôpital La Charité, has employed a mixture of ferrocyanide of potassium and urea in the treatment of five cases of intermittent fever. In two of these it was successfully used, and in two unsuccessfully.—*Journal de Chimie Médicale*.

* * * There is no reason to suppose that it can be used as a substitute for quinine with any prospect of success.

MEDICAL GAZETTE.

FRIDAY, DECEMBER 20, 1850.

AN accurate statistical return of the comparative mortality in the Metropolitan and Provincial Hospitals would throw great light on the results of practice, and be attended with great benefit to medical science. The comparison might not merely extend to the relative mortality in the different institutions of this country, but to the proportionate number of deaths in these, and in the great hospitals of Paris, as well as of other continental cities. At present, however, we have no accurate data for such calculations; and great care is required in instituting comparisons, because by the assumption of an incorrect basis, an undue prejudice may be created against the medical superintendence of certain institutions. The plan adopted by the Registrar-General, of publishing a weekly return of deaths in the different metropolitan hospitals, is of no statistical value whatever, unless this be connected with a quarterly or yearly summary of the number of patients actually admitted into each institution.

With a laudable desire to arrive at some sort of conclusion on this important subject, Dr. Webster, in a pamphlet now before us, takes the number of deaths in hospitals for six months, as returned by the Registrar-General, and compares these deaths with the number of *beds* which each hospital is supposed to contain.* The conclusions at which he has arrived are as follows:

"1st. One death in every 21.75 of the total mortality throughout London, or 4.60 per cent., took place in the eleven general hospitals during the last six

months. 2d. One patient died for nearly every three beds, speaking in the aggregate. 3d. The highest rate of mortality generally occurred in the smallest hospitals. 4th. With one exception, the lowest comparative ratio of deaths was observed in the large or more populous institutions. 5th. The fewest deaths, in reference to the published number of beds, was reported from the Free Hospital; and 6th. The largest comparative mortality, according to the same calculation, occurred at University College Hospital."

The table from which these deductions have been made is elsewhere printed*. The general result from eleven hospitals is that there are 3228 beds, and there were in six months 1051 deaths, making 1 to $3\frac{1}{4}$ beds. The mortality at UNIVERSITY COLLEGE thus appears to be *one death to every* $1\frac{1}{2}$ bed, while at the FREE HOSPITAL there is only *one death to every* $6\frac{1}{2}$ beds!

The author appears to be aware that this mode of calculating deaths in hospitals may lead to fallacy; but, as we infer from his observation, he does not perceive the entire unsoundness of such a mode of computation. In remarking on the numerical results, he observes:

"On the other hand, when comparing one hospital with another, it is curious to observe that the mortality was nearly the same at St. Bartholomew's and Guy's, the two largest institutions of the kind, and having each the same number of beds—viz. 580. Again, at St. George's and the London hospitals, each having 320 beds, one being situated at the west end of London, the other at the east, where an immense number of serious accidents constantly occur, and certainly very many more than in the neighbourhood of Piccadilly, there is not much difference in the rate of mortality. This is, however, in favour of the latter hospital, although still inferior to the Middlesex, St. Bartholomew's, and Guy's, but especially to St. Thomas's Hospital, where the ratio of mortality was less than at any other similar institution, with the sole exception of the Free Hospital, as previously stated. 1 and

* On the Health of London during the six months terminating September 28th, 1850. Read before the Medical Society of London, and reprinted from the London Journal of Medicine.

fully aware that these calculations must not be taken as absolutely free from all fallacy, since the admissions of patients may be more numerous at one establishment than at another. But I think that this argument, if it has any force, would rather militate against the smaller and more modern hospitals, to which letters of recommendation from a governor, unless for accidents, are often required to ensure the reception of an in-patient; while at the two ancient Royal Hospitals of the city, and at Guy's, where the rate of mortality has been found to be lower, the facility of admission is greater, and the applications, consequently, likely to be more numerous. The subject here mooted is both so important and instructive that it deserves further inquiry: indeed, it is solely with that object I have now made these imperfect remarks, and based them upon the numbers contained in the average table, which, I believe, is the first ever compiled in illustration of the results obtained at the eleven general hospitals of London, viewed comparatively."

It is, we think, obvious that the table collected by Dr. Webster is merely calculated to show the mortality of beds, and not of patients; and that, as the relative number of admissions of patients within a given period of time is not even hinted at, it is impossible to make any use of these figures in computing the comparative mortality, even admitting that the number of beds assigned to each of the eleven hospitals is correct, and that the beds are always occupied.* The number of beds occupied in an hospital is very well known to be open to great fluctuation; the same bed may be occupied at one hospital by three or four different patients, and at another hospital by only one patient during the same statistical period. Thus this table, which would have the effect of causing all claimants for medical and surgical assistance to rush to the Free Hospital, and fly from University College Hospital as from a Pest

* It has been computed that in the large hospitals each bed, on an average, receives from nine to ten occupants per annum.

House, errs in taking no account of these material elements of the inquiry. If it happened that during the period of six months only one-half of the Free Hospital beds were occupied by patients whose cases were of a protracted kind, and required lengthened treatment, while the inmates of University College Hospital were frequently renewed, the deaths in the latter, arising perhaps from the greater number of patients, and the severity of the cases received, would appear very high if compared with the fixtures of the hospital—namely, the beds; while compared with the numbers actually admitted and treated, the mortality might be no greater than at the Free Hospital. In short, the comparison of deaths with beds, can show no more than the deaths compared with wards; nor is there any method of correcting so defective a basis of calculation, by any subsequent allowance for the situations of hospitals, or the class of persons who apply for relief. The only part of Dr. Webster's table which can be received as approximately correct is the column of deaths, which, as it has been compiled from the Registrar's return, may be taken to represent the Hospital mortality of London for six months, so far as the Registrar can procure information on the subject. If we double these numbers, we obtain the annual mortality in the eleven Hospitals of London, as under. The figures, however, are open to correction, by taking a period of several years:—

Hospitals.	Annual Deaths.
St. Bartholomew's	360
Guy's	328
London	240
St. Thomas's	230
St. George's	212
Middlesex	172
Westminster	158
University College	158
King's College	132
Charing Cross	72
Free Hospital	44

In order to arrive at anything like a

fair comparison of these numerical results, it is of course necessary to show, not only the number of patients admitted into each institution, but also the class of applicants,—whether labouring under severe accidents, or acute or chronic diseases, or whether the cases be of a kind in which destitution and disease are equally combined, and the latter not of a serious nature. A hospital situated in the vicinity of the places where accidents frequently occur may have a higher rate of mortality than one in the heart of the metropolis merely as a result of its local position. Information on these last-mentioned points it is very difficult to procure, but the first postulate—namely, the annual number of admissions, may be in some cases obtained; and we agree with

Dr. Webster in thinking that it is the duty of those who are connected with these large institutions to publish a yearly summary of cases admitted, the number of deaths, and other particulars throwing light on the treatment of disease. To a certain extent this has been carried out for many years by the Governors of the London Hospital, and in a less perfect manner by those of St. Bartholomew's and St. Thomas's.

In Paris a quarterly return of the *admissions and deaths* of patients in the public hospitals is regularly made. We subjoin the Parisian table for the second quarter of 1850. It may not only serve for guidance in these statistical inquiries, but it will hereafter enable us to compare the mortality of the London with that of the Parisian hospitals.

Deaths in the Hospitals of Paris, exclusive of Infirmeries (Hospices), during the Second Quarter of 1850.

Months.	In-Patients on the 1st of the Month.	Patients admitted during the Month.	Total In-Patients.	Patients discharged during the Month.	Deaths.
April	6034	7328	13362	6752	596
May	6014	7129	13143	6483	661
June	6009	7174	13183	6800	559
Totals during the Quarter . . . }	18057	21631	39688	20035	1806

If we deduct the number of patients discharged during the quarter from the total of those admitted and already in the hospitals, it will be perceived that there were during the quarter 19,053 inmates and 1,806 deaths; thus giving a mortality of 10·8 per cent.

According to Dr. Webster's table, after King's and University College, the London and Westminster Hospitals occupy a most unfavourable position as to the rate of mortality: in fact, taking round numbers, the patients who die in these institutions are equal to half the number of beds contained in them—i. e. for every two beds and a fraction one death must be reckoned! It would also

appear that the deaths in the London are comparatively twice as numerous as those in St. Thomas's Hospital, and that the mortality at St. George's is rather less than in the London Hospital. We have procured some authentic documents which will tend to show the inaccuracy of the results to which this faulty mode of computation must necessarily lead. The number of beds in each hospital is taken from Dr. Webster's table, with the necessary correction, that at the London they have amounted, since 1847, to 400, the number actually occupied by patients varying at different periods from 396 to 253.

Hospitals.	No. of Beds.	Total In-Patients.	Deaths.	Deaths per Cent.	Accidents.	Deaths from Accident.	Deaths from Accident per Cent.
1844.							
St. George's . . .	320	3284	293	9	1120		
London . . .	320	3691	224	6	2140	79	3½
1847.							
St. Bartholomew's	580	5801	428	7½			
St. Thomas's . . .	487	3709	283	7½			
London . . .	400	4159	276	6½	2396	73	3
1848.							
St. Bartholomew's	580	5826	480	8½			
St. Thomas's . . .	487	4340	276	6½			
London . . .	400	4185	264	6½	2442	80	3½

From these returns it will be perceived that, when the deaths are compared with the in-patients actually received, and not with the beds, the comparative mortality of the London Hospital does not reach seven per cent., and at least three per cent. of the deaths arise from accidents! In these periods, which are not selected, but taken merely because authentic comparative returns are procurable for the years mentioned, the relative mortality of St. George's, St. Bartholomew's, and St. Thomas's, invariably exceeded that of the London.

The mortality at the London Hospital has of late years undergone a very considerable reduction. Since the year 1846 the per centage of deaths from accidents, has been equal to nearly one-half of the per centage from all other causes. The table subjoined, the accuracy of which may be relied on, throws an interesting light on this question.

As a general average of the returns for the fifteen years, it may be stated that there were for each year 3471 in-patients; and, including the cholera year (1849), 292 deaths; thus giving a mortality of 8·1 per cent. If we divide the maximum number of beds occupied at any one time during this period (396) by the average yearly deaths, we shall find that the deaths are to the beds in the alarming proportion of 1 to 1·4—i. e., three times as numerous

as at St. Thomas's Hospital, according to the table published by Dr. Webster. But when we compare the yearly deaths with the yearly *occupants of the beds*, the deaths at the London are fewer by 1·7th, or 14 per cent.!

Return of the Number of Patients admitted annually into the Wards of the London Hospital, from the year 1835 to 1849, both inclusive, and also the number of deaths in each year.

Date.	No. of patients.	Deaths.	Per cent.	Per centage of deaths from accident.
1835	2785	277	10	
1836	2815	309	10	
1837	2961	418	14½	
1838	2987	371	12½	
1839	3247	305	9½	
1840	3389	296	9	
1841	3308	331	10	
1842	3300	260	8	
1843	3530	244	7	
1844	3961	224	6	
1845	3625	228	6½	
1846	4092	230	7	4½ p. cent.
1847	4159	276	6½	3 "
1848	4185	263	6½	3½ "
1849	4090	298	7½	4 "

We shall shortly return to this subject, and consider the comparative mortality at the other London hospitals.

Reviews.

The Races of Man; and their Geographical Distribution. By CHARLES PICKERING, M.D., Member of the United States Exploring Expedition. A new Edition, to which is prefixed, *An Analytical Synopsis of the Natural History of Man*, by JOHN CHARLES HALL, M.D., &c. 8vo. pp. 345. London: H. G. Bohn. 1850.

THE objects of a medical journal scarcely permit an extensive notice of this very interesting work, and we therefore limit ourselves to a brief analysis of its contents.

Dr. Pickering, after a close observation of the varieties of men in different parts of the world, visited by the Exploring Expedition, arrives at the conclusion that eleven races may be distinguished in the countries visited by him, and that these may be arranged in four orders, according to the colour of their complexion; thus,—White, Brown, Blackish-brown, and Black. Of these, the first embraces Arabians and Abyssinians; the second, Mongolians, Hottentots, and Malays; the third, Papuans, Negrillos, Indians, and Ethiopians; the fourth, Australians, and Negroes. The distribution of these varieties over the world is represented by a coloured map, after Dr. Prichard's plan. These several tribes are mentioned in the order in which the countries they inhabit were visited; and a short history of the characters, habits, &c., of each tribe is given.

Several allied subjects are also treated of: such as the relations of races, the geographical progress of knowledge, migration by sea and land, the origin of agriculture, zoological deductions, distribution of animals and plants, and lastly, the introduced animals and plants of Egypt.

It is needless to say more respecting this volume, than that it contains a large amount of valuable information, with respect to aboriginal tribes, collected on the spot by a careful and skilful investigator; and that it forms, therefore, a most important contribution to ethnology.

Dr. Hall's synopsis presents a brief but clear exposition of the *Natural History of Man*, without which the

general reader would not be able fully to appreciate the value of Dr. Pickering's work. The present state of the question as to the origin of man from one or more pairs of parents, is ably and lucidly stated by Dr. Hall.

We must do this gentleman the justice to say that he has rendered the work as interesting and instructive to the professional as to the general reader.

The Commercial Hand-Book of Chemical Analysis, &c. By A. NORMANDY. 8vo. pp. 640, with illustrations. London: Knight, Foster Lane. 1850.

DR. NORMANDY has here produced a very useful manual for the guidance of the chemist in detecting the numerous adulterations to which articles of food, commerce, and manufactures, are subjected. A book of this kind has been long wanted, and it is surprising, considering the demands now made upon science by merchants and manufacturers, that such a treatise has not hitherto been published. The small manual of Accum was a very imperfect production at its first appearance, and it is now quite obsolete.

Dr. Normandy arranges the various substances treated in his book in alphabetical order, thus greatly facilitating reference. The list of substances is very copious, and comprises, as far as we can judge, all that are likely to give rise to the necessity for chemical examination. Tables of analysis of the strength of different products and appropriate illustrations are offered to those articles which require them.

From our perusal of various sections of the work relating to the adulterations of food, we consider that this book will prove a most useful companion to the chemical student.

Influence of Physical Agents on the Development of the Tadpole, of the Triton, and the Frog. By JOHN HIGGINSBOTTOM, Hon. Fellow of the Royal College of Surgeons of England. Reprinted from the *Philosophical Transactions*, part ii. for 1850. 4to pp. 8, with a plate. London: R and J. Taylor. 1850.

A series of experiments is here related, by which the absence of lig

retarding the development of the tadpole, while temperature exerts an important influence on its growth. The plate which accompanies this essay presents, by a simple and easy diagram, the respective influences of these two physical agents. This contribution to natural history and physiology will be very acceptable to the students of these sciences.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, Dec. 10, 1850.

THE PRESIDENT in the Chair.

Case illustrating the Difficulties of Diagnosis of Morbid Growths from the Upper Jaw; with Remarks. By PRESCOTT HEWETT, Assistant-Surgeon to St. George's Hospital, &c.

THE patient, a man *æt.* 25, was admitted into St. George's Hospital under the care of Mr. P. Hewett, in May 1848, with a large tumor, of an irregular shape, occupying various regions of the left side of the face. Presenting every appearance of having originated in the antrum, this tumor was found in the front and back part of the cheek, in the temporal fossa, in the orbit, and in the nostril extending to the back part of the pharynx; round in shape, but lobulated, it was firm and elastic to the touch, perfectly moveable, and in the nostril of a dead white colour and glistening appearance. The skin, conjunctiva, and mucous membrane of the nose were quite healthy, and no enlarged glands could be detected in any part.

The history of the case was, that six years previous to his admission into the hospital the patient was troubled with a disease, supposed to be a polypus of the nose, which had been easily removed with the forceps; subsequently, however, the cheek began to swell, and the tumors gradually made their appearance in the regions in which they were found. All this had occurred without any pain, and with very little inconvenience. A year ago caustic had been extensively applied in two different places, large cicatrices marking the spots: this treatment had produced no effect on the disease, and no fungating growths followed the application. At different times there had been extensive bleed-

ings from the nose, which had somewhat reduced the patient.

At a consultation of the surgeons of the hospital, it having been resolved that in all probability the disease was of the fibrous kind, and connected with the antrum, the removal of the upper jaw was decided upon. Dr. Snow, to whom the surgeons of St. George's are so much indebted for the able manner in which he, for a long time, administered chloroform at the hospital, having kindly undertaken to give it on this occasion.

The patient being seated in a chair, the operation was performed in the usual manner; but on removing the superior maxillary and malar bones, it was discovered that the disease was not connected with the upper jaw; it was altogether behind it. The larger portion of the tumor was dissected from off the pterygoid process, to which it was firmly attached. Those portions which were in the orbit and temporal fossa were removed without difficulty, being for the greater part simply connected with some very loose cellular tissue. The patient having become faint, was placed in the horizontal posture, and a small quantity of stimulant administered, after which he soon rallied. The portion of diseased structure in the back of the nostril was then removed with a strong pair of curved scissors. The pulse having again failed, the patient was at once laid on a bed and carried into an adjoining room: different restorative means were made use of, and he appeared to rally somewhat; but shortly afterwards, as the breathing became embarrassed, an opening was at once made into the crico-thyroid membrane; and, as a last resource, an attempt was made to carry on artificial respiration with a tube, but every effort proved of no avail; the patient soon died.

But few vessels were met with during the operation, and no great amount of blood was lost. Little or no bleeding followed the incision in the neck.

A careful examination of the bones removed during the operation, shewed that in the superior maxillary the antrum was all but obliterated, the posterior wall of the sinus having been forced, by the tumor lying behind it, against the anterior one; there was merely a chink left, the cavity of which was quite free, and lined by healthy mucous membrane; the malar was much more curved than natural. The structure of both bones was perfectly healthy. The tumors were of a purely fibrous character. At the dissection of the body it was made out that the tumor had originated in the roof of the left nostril; its main point of attachment having been to the under part of the body of the sphenoid, and inner

surface of the pterygoid process. Portions of diseased structure were still found in the sphenoidal sinuses, as well as at the upper and back part of the septum nasi. Some loose bits were also found deep in the temporal fossa, and at the back of the orbit; these were lying in the cellular tissue; they were all connected to each other by slender pedicles, one of which passed through a hole in the perpendicular portion of the palate bone; that in the orbit had reached this situation by creeping through the spheno-maxillary fissure. The bones were throughout healthy in structure. The tissue of the growth was purely fibrous.

The trachea and bronchial tubes, even to their minute ramifications, contained a quantity of frothy blood; the structure of the lungs was crepitant throughout, but each section presented numerous small dark spots of ecchymosis produced by some of the air-cells having been also filled with blood; these organs were otherwise free from disease. The heart was healthy; its cavities contained small black clots, but the greater part of the blood was thin and fluid, and did not coagulate on exposure to air. The other viscera were quite healthy.

In his remarks, Mr. Prescott Hewett principally drew the attention of the Society to the great difficulties which, at times, were found to exist as to the correct diagnosis of the precise region in which a tumor of the upper jaw had originated. Of these difficulties the present case afforded a good illustration. The history of the patient, and the various regions in which the tumor existed, had led to the conclusion that the disease, having sprung from the antrum, had gradually burst through the walls of this cavity, and thence spread to the spots where it was found. The operation and the subsequent dissection proved, however, that the antrum had not been the starting point of the disease. Mr. P. Hewett had little or no doubt that the morbid growth had first begun in the nostril, and had subsequently reached the pterygo-maxillary fossa, either by making its way through the spheno-palatine foramen, or by breaking down a portion of the palate bone. Once in the fossa, the subsequent progress of the tumor may easily be traced; it passed into the orbit through the spheno-maxillary fissure, and, in the face, it had in some parts made the bones yield, and, in others, it had so completely moulded itself to their shape, creeping over their cutaneous surface, that the outlines of the bones were scarcely discernible. Mr. P. Hewett's remarks were altogether confined to tumors of a fibrous character.

The morbid appearances observed about the lungs led Mr. P. Hewett to ask the question, whether the administration of

chloroform was advisable in operations about the mouth where there was likely to be a certain amount of bleeding. He had no doubt that the blood found in the lungs had got there by passing through the glottis; and he doubted very much if such would have been the case had no chloroform been used. Many surgeons, fearing this accident, had of late not failed to condemn altogether the use of chloroform in these cases; but some, being unwilling to submit their patients to such serious operations without it, had adopted a middle course, administering this agent in the first steps of the operation only, hoping thus to avoid all risk. It remained still to be proved, however, whether, even with this precaution, there might not be danger in using anaesthetics in some operations about the mouth.

Mr. FERGUSON said that, in common with every member of the Society, he considered this paper most interesting, as illustrating the differences of danger in those cases; but it was clear the tumor turned out different from what was supposed. At first it was said to be situated in the superior maxillary bone, but afterwards it proved to be only in connection with it; and there could be but little doubt of its being situated behind the antrum. No allusion was made to the shape and form of the superior maxillary; and there being no distortion of the alveoli or nostril, would lead to the opinion that the tumor was in the antrum, a matter of great importance where there was no alteration in front: it was evidently deep-seated, from the expansion of the zygomatic arch. In conclusion, he would not let the opportunity pass without giving an opinion respecting the use of chloroform in such cases. From numerous cases of protracted operations about the mouth, in which he applied it to both mouth and nostrils, and renewed it when its effects passed off, he considered he never had seen any case deterring from its use. At first he supposed such operations as the one described those in which it would not be applicable, and in a similar case at first did not try it, but soon discovered from using it in operations on both the jaws as well as mouth, where blood would flow back into the trachea, that no evil result had arisen: he wished to ask Mr. Hewett how long the operation lasted, as it might be tedious even in the hands of the most experienced, and we should weigh well all the circumstances which may cause death in such cases.

Mr. HEWETT did not exactly understand Mr. Ferguson's question, but he thought out of their places

minutes; but from fainting of the patient could not say exactly, but imagined about twenty minutes altogether.

Dr. WEBSTER asked whether chloroform was the cause of death, as in all cases where death so occurred the blood was found fluid; and in France it was stated to be black, and that air was found in the heart and veins.

Mr. HEWETT replied that the blood was fluid and dark coloured, and that if chloroform caused death in this case it was by suffocation.

Dr. SNOW said he was sure the blood did not get in during the operation, from the patient experiencing no difficulty of breathing, and that he had since administered chloroform in five or six cases: one for tumor of superior and one of inferior maxilla; also in other cases of similar difficulties, as polypus, &c.; but that there was no better test of its applicability than in operations for hare-lip. He had used it in twenty such cases, and had seen as much appearance of suffocation and stuffing when it had not been used. In this case there was not enough blood found in the lungs to cause suffocation: he thought the blood got in after the operation, while the patient was lying in a state of collapse, as there was oozing of blood up to the time of his death. From experiments on animals he found, as in the case of a cat held for two minutes under water, that none was drawn in until the animal was almost dying; and in a kitten killed by chloroform, the trachea was not stained. In asphyxia from drowning the lungs do not fill with water. In animals killed by chloroform the blood was found semi-coagulated; and he thought the fluidity in this case was attributable to the artificial respiration. The glottis retains sensibility as long as the patient has sense to breathe, and he believed the opinions respecting the use of chloroform were as much in favour of as against it.

Mr. H. C. JOHNSON stated that three grounds of death had been raised unconnected with chloroform:—1st. The length of the operation; 2dly. The inhalation of blood during syncope; and 3dly. The operation for artificial respiration. He said that the operation was not longer than usual, in fact the first step quicker than customary in operations about the face. He confessed the syncope was very severe; but although he had seen many such cases, he had never witnessed an instance of blood being received into the trachea. And in answer to the third, it was performed when the patient was almost moribund, and he did not consider that any blood escaped. From the result of this case he would abandon the use of chloroform in all similar ones; he was of opinion that death

was caused by the inhalation of a quantity of blood.

Mr. BARLOW was willing to admit Dr. SNOW's care in the administration of the chloroform, but there was no way so easy to account for death as its influence; and although it was gratifying to know Mr. Fergusson's success, he considered no agent diminishes muscular irritability like it; and although in five cases it may not have this effect, yet it may in the sixth. A frog under its influence cannot be so easily galvanized as one that is not; and he believed Mr. Hewett correct in stating, that if the glottis had been sufficiently active, this sudden result would not have occurred.

Dr. MARSHALL HALL divided the effects of chloroform into three stages: in the first of which voluntary motion is diminished; the second, in which respiration fails; and the third, in which circulation fails;—and from the quickness of its fatality in experiments on animals, considered it a most fearful poison. He feared many of its fatal results in private practice have not been made known, and considered if its influence is carried beyond its effects on the cerebrum, its application was certainly dangerous. In cases of asphyxia there are more efforts of expiration than of inspiration. He thought it was ill-judged to have changed from ether to chloroform, as the former is less dangerous, and as capable of producing anæsthesia. If a patient is in a state of anæsthesia, he can be moved; and the mesmeric experiment performed some five years since to produce this state had been confessed to Dr. Hall by the party operated on as all a trick.

Dr. COPLAND asked whether the shock might not be greater when the system is insensible than under other circumstances, and believed it is so; also, that reaction is more salutary when chloroform is not used, for suppose you deaden sensibility, in that case the shock is greater. He thought the source whence the blood came in this case was not ascertained. Under chloroform the irritability of the small vessels being impaired you might have exudation of blood from the bronchi. He inquired whether the shock was great.

Mr. TRACEY had never seen a case of death when the patient had rallied from its effects, or a case where blood got into the lungs from operations about the mouth, although he administered chloroform frequently.

The PRESIDENT asked Dr. SNOW, as the patient never rallied after the cessation of hæmorrhage, what prevented chloroform being the cause of death.

Dr. SNOW in answer said the patient's breathing not being stertorous, or muscles relaxed, and only being in, according to his

division of its effects, the third degree of narcotism (he making five). He quite agreed with Dr. Hall in the order of its effects.

Mr. BARLOW considered there could be no other cause of death. Although the operation itself, the hemorrhage, the extent of the tumor, and oozing of blood after the operation, all shewed the case to be a most severe one, and would of course go greatly against the patient.

Dr. WEBSTER had got an answer to the blood being fluid, but not as to air being found in heart or veins.

Mr. HEWETT answered that there was no air in the heart, but that the veins were not examined.

Mr. CHARLES HAWKINS.—It is a point of great importance as to whether we are to use chloroform; and I consider that the suddenness of death in this case was such as would result from air getting into the veins, and should like to know what the cause of death was. It had appeared to him, until Dr. Copland's observation, that chloroform lessened the shock; but never saw a patient die so suddenly as in the present case.

Mr. CESAR HAWKINS said it was very natural Dr. Snow should throw off the blame from chloroform, but he felt convinced that death was caused from blood getting into the lungs, although this was rare; but that it was evidently increased by chloroform. In St. Bartholomew's and St. George's Hospitals, it had been used in every operation, and no direct death had occurred from its use, but it is never used in teeth extraction or minor operations,—deaths only having happened from its use in the Borough hospitals, twice at Guy's and once at St. Thomas's, and the latter was occasioned by its inexperienced administration.

Mr. SOLLY.—In the fatal case at St. Thomas's, no proper person was appointed to administer it, and without any warning the heart became paralyzed: he always made allowance for cases similar to Mr. Hewett's, in which he considers that loss of blood producing syncope the heart becomes paralyzed. He would not use chloroform in such cases. He concluded by asking whether the patient was sitting or lying?

Mr. HEWETT.—Sitting.

Mr. BENJAMIN PHILLIPS remarked that before the use of chloroform we had a great many cases of sudden deaths.

The PRESIDENT announced that the next meeting of the Society would take place on January the 14th, 1851.

PATHOLOGICAL SOCIETY OF LONDON.

Dr. LATHAM, PRESIDENT.

December, 3, 1850.

MR. HENRY CHARLES JOHNSON exhibited the preparation of

A Bladder, removed from a Man at 72, who had undergone the operation of Lithotripsy more than once, and with which was connected a Large Sac, at its upper part, filled with Small Calculi.

About three years previous to his death (having suffered many years from symptoms of stone in the bladder), he underwent the operation of lithotripsy in St. George's Hospital, and left the hospital apparently well. Prior to the operation the urethra was gradually dilated till it would allow of the passage of a large bougie, size No. 20.

About two years after he quitted hospital the former symptoms of stone returned, and became troublesome; the urine alkaline, and filled with ropy mucus, and being passed constantly; the general health much shattered, and the pain preventing sleep at night.

He was again admitted into the hospital, and, under treatment, somewhat improved, so that the operation of lithotripsy was again performed, and several small calculi were broken up.

For a fortnight after the operation everything went on well, and numerous fragments and sand were daily passed. A month after the operation he suffered more pain in passing the fragments, and the urine was more ammoniacal and ropy; his tongue became moist and dry, and he gradually sank and died about six weeks after the last operation.

Examination.—The kidneys were imbedded in much fat; their surfaces dark, and dotted with points of lymph and pus, the right one being in the most advanced stage of inflammation, with more evidence of pus mixed with the lymph: in its substance was a small abscess filled with pus. The mucous membrane of both pelvis was almost black, and covered with bloody secretion. The ureters were dilated, and their lining membrane in the same condition of congestion and inflammation. The bladder was filled with bloody urine, and much corrugated internally, and the muscular coats hypertrophied; the mucous membrane inflamed. Above and to the right of the bladder was a small pouch, which communicated with its cavity by a contracted opening, and which was filled

with calculi of a triangular shape and soft consistence, formed chiefly of the phosphates; the bladder itself contained some fragments of calculi. The prostate gland was much enlarged. Some fragments of calculi were found impacted in the membranous portion of the urethra; there was no suppuration external to the urethra.

In this specimen Mr. Johnson called the attention of the Society to the circumstance of the impacted portion of stone in the urethra, an accident of frequent occurrence, and which generally requires an incision in the perineum for its relief, but in the present instance would have been of no avail, as the patient died from abscess in the kidney, and did not present the ordinary symptoms of impaction within the urethra.

Mr. POLLOCK exhibited some specimens showing

Portions of Calculi impacted in the Bladder after the operation of Lithotripsy.

One specimen was from a man, aged 62, admitted into St. George's Hospital, under the care of Mr. Caesar Hawkins. He had suffered from symptoms of stone in the bladder for two years. His water was occasionally tinged with blood, and the irritability of the bladder considerable at times. He appeared in good health. The stone was readily detected, and was apparently of considerable size. It was crushed by Mr. Caesar Hawkins without any difficulty, and without much pain; and before the instrument was withdrawn the fragments were broken down ten or twelve times. The stone was a very hard one. One fragment was fixed into the eye of the instrument, and gave pain in its passage through the urethra, meeting with some difficulty in its withdrawal at the orifice. He passed several fragments during the few succeeding days. On the evening of the operation he was attacked with severe rigor, followed by profuse sweating. Three days after the operation he was again attacked with severe rigor, followed by profuse sweating. The catheter was used daily. The urine was alkaline, foetid, and contained much mucus and sand, and was tinged with blood. The bladder was washed out with warm water daily, and many fragments of stone brought away by this means. A succession of severe rigors and profuse perspirations recurred daily till the sixth day, when the irritative fever was considerable: he was better. Subsequently the urine was again dark, alkaline, and passed with much straining. The quantity of blood in the water increased. He died on the twelfth day after the operation.

Examination.

Thorax.—Evidence of slight recent pleurisy on left side. The surface of lung dotted with spots of congestion, in many of which were small specks of lymph or pus. The spots of congestion existed generally throughout the structure of the lung. The right lung was gorged with serum, and much congested, and softened posteriorly. The heart flabby. The blood chiefly fluid.

Abdomen.—The kidneys were flabby in texture, and contained a number of small cysts throughout their entire substance, and in both patches of congestion, in the centre of which were specks of lymph and pus. The bladder much contracted and thickened; its lining membrane thrown into irregular folds, which were slightly coated with phosphate of lime. The mucous membrane greatly inflamed, and that lining the membranous portion of the urethra sloughy and shreddy; small ulcerated openings passed a little way into the surrounding tissue. The bladder contained numerous fragments of calculi; one very large, about a third of the original stone. There were also several small pieces in the membranous portion of the urethra. The prostatic veins were inflamed, and blocked up with coagula: the prostate was much enlarged.

The second specimen was from a man, æt. 32, admitted, under Mr. Cutler, with all the symptoms of stone in the bladder, and for which he underwent the operation of crushing. At the first operation it was broken several times, nor did any disturbance follow. The fragments were again broken down twelve days after the first operation. This time a slight rigor followed the withdrawal of the instrument, and soon afterwards a piece of stone became lodged in the urethra in front of the scrotum, which was cut down upon and removed. A fortnight after the second operation the fragments were again crushed, and several portions were extracted at the time, and much followed through the catheter. Considerable irritative fever followed, with rigors and profuse perspirations, and he died about three weeks after the last operation.

Examination.—Left pleura filled with yellow serum mixed with much lymph. Lung much congested, and contained several foul abscesses. Recent pleurisy on right side. Right lung inflamed, and contained several abscesses. Blood generally fluid.

Abdomen.—Liver natural; kidneys rather large; veins surrounding bladder, prostate, and rectum congested, and many of them filled with pus; a foul abscess in the perineum communicating with the urethra at the membranous portion through several

openings; the bladder contracted; the mucous lining dark coloured; some fragments of calculi in the bladder; the membranous portion of the urethra was ulcerated, and communicated with the abscess in the perineum: about three and a half inches beyond this ulceration another lacerated opening existed in the urethra at its lower part, which communicated externally: this had been made during life to extract the fragment of stone.

Mr. Pollock alluded to a third case in many respects similar to the two preceding ones, in which a man underwent the operation of lithotripsy two or three times, and subsequently died, having suffered from great irritation and constitutional disturbance following the last operation. On examination, a large portion of stone was found fixed in the membranous portion of the urethra, having partly worked its way out through the floor of the urethra, where a large opening existed, communicating with a foul abscess external to the urethra.

The cases presented to the Society were specimens of one of the accidents attendant upon the operation of lithotripsy, and deserved attention as specimens of an accident which, fortunately, did but rarely prove fatal. If the specimens were evidence of any one point in common, they were evidence of the tendency that occurred after this operation for fragments of calculi to become lodged and retained in the urethra after the crushing of the stone in the bladder. The case exhibited by Mr. Henry Charles Johnson was evidence of this fact; but in his case the occurrence was not attended by unfavourable symptoms, nor did it apparently add to any of the causes of death. The urethra in this case had been most amply dilated, and had not been apparently lacerated by endeavouring to withdraw the lithotrite loaded with fragments of calculi.

In the other specimens exhibited the fragments had most probably lodged in some lacerations of the urethra, and had there set up the mischief which was found after death. In this operation every precaution should be taken to avoid injuring the urethra when the lithotrite is withdrawn from the bladder. With every precaution, however, this accident cannot always be avoided, as when a piece of stone is fixed in the eye of the instrument and cannot be removed until the instrument is withdrawn.

The stoppage of a fragment of stone is not an uncommon event after the operation of lithotripsy; but the danger occurs, first, from the stoppage taking place in consequence of a laceration of the urethra, and, secondly, when the stone, not being detected, remains in the urethra. When the stoppage of a portion of stone is detected,

it may be either taken away or pushed back into the bladder, or else removed by an incision. The removal of the impacted portions by incision in either of the cases related by Mr. Pollock would have availed nothing. The operation was proposed, but not performed, as the patients were evidently dying from the effects of absorption of pus.

MEDICAL SOCIETY OF LONDON.

Dec. 14, 1830.

DR. J. R. BENNETT, PRESIDENT.

Aneurism of the Arch of the Aorta.

DR. LANKESTER exhibited an aneurism of the arch of the aorta, extending over the whole of the transverse portion of the arch; the heart being healthy and small, the lungs also healthy. He considered the disease had been between six and seven years in progress, and he had noticed that in proportion to the enlargement of the cyst the sufferings of the patient seemed to diminish. Auscultation discovered the second sound only to be accompanied by a slight *bruit*.

Non-United Fracture—Resection.

MR. GAY produced the opposite ends of an ununited fracture of the femur at the upper third, of twelve months standing. After the trial of various means, he had resorted to the operation of resection. The result not being successful, at the end of three months he amputated. The patient died. The specimen exhibited scarcely any attempts at reparation. The patient before the occurrence of the fracture was a fine, healthy man.

Mr. Gay stated in answer to a question from Mr. Canton, that the *permanently* contracted state of the muscles was the chief obstacle to the re-union of the bone in the various measures tried by him before the last resource to resection, the ends of the bone being thereby drawn away from each other.

MR. HAYNES WALTON read a paper upon

Excision of the Head of the Femur.

After remarking upon the diversity of opinion concerning the propriety of this operation, the author said, the leading question was, at what stage of the disease the operation should be performed. There were two considerations to be taken into account—1, the local; 2, the constitutional. With reference to the first, he thought, when the discharge was excessive, thin, dark, and of bad odour: in respect to the second, when there was much hectic

fever. If, on examination, disease of the internal organs could not be discovered, especially of the lungs, the operation should take place. There was a question whether disease would not sooner or later come on in these from the effects of the local disorder upon the constitution, if the local mischief were not removed.

The author did not consider the acetabulum to be so often diseased in morbus coxae as the head of the femur; and that, when diseased, it had greater power of reparation.

He believed non-dislocation of the head of the femur to be diagnostic of soundness of the acetabulum; and that, by exploratory incision, or by passing the finger through a sinus, the state of the acetabulum might often be discovered. If there were no disease in the acetabulum, the operation would most probably be successful, although cases had turned out well where there had been disease in that portion of the joint. Out of fourteen cases, twelve of which had been collected from different sources—the other two having occurred in his own practice—six had proved fatal: one had died from renal disease, another from hæmorrhage from the profundic vein, another from diarrhoea: the cause of death in the other three was not given.

The operation was in reality much less severe than it appeared to be: the wasted state of the parts facilitated the operation, while the loss of blood was remarkably small.

The author did not advocate removal of the trochanter as well as the head of the bone. The long interrupted splint was the best apparatus to apply after the operation.

Mr. B. TRAVERS gave great weight to the opinions of Cooper, Cline, and Hunter, all of whom were averse to the performance of the operation in question. He thought that confidence should be placed in the reparative powers of the body, and that, if the case were really curable, the operation would not be required. Even if the operation were successful the limb was of but little service. From all he had read, heard, and seen, he was of opinion that the successful cases would have got well without interference with the knife. The specimen that had been handed round showed attempts at reparation had been made in those where the operation had succeeded.

Mr. DAMPIER agreed in the main with Mr. Travers.

Mr. CLARKE did not consider a case to be cured even if the patient lived twelve months after the operation, and that death was hastened by the operation.

Mr. CHALK spoke of the difficulty of diagnosing this disease from lumbar and psoas abscess, and questioned if the disease were removed with the head of the bone.

Mr. GAY could not coincide with Mr. Travers; the process of reparation in bone was so tardy, that the knife should be employed to assist nature, and that by its use much constitutional irritation could be spared the patient. He would not advise the use of the knife when the manifestation of scrofulous disease was very active.

Mr. H. SMITH mentioned the result of some successful cases. One, a boy, æt. 13, operated in 1845, was now hearty and active, and could walk from Holloway to London. Another, operated on two years ago, a female, æt. 13, was seen yesterday by him, and found in a very comfortable condition, and could walk a mile without assistance. Both were Mr. Fergusson's cases. Another, Mr. Morris's (of Spalding) case, operated on in 1849, was quite well, had perfect motion with the thigh, and could walk a short distance.

He had seen mistakes made concerning the position of the head of the bone, and the operation given up in consequence after the first incision had been made. The operation was advisable, because by preventing ankylosis the mal-position of the limb was obviated.

Mr. LLOYD had paid considerable attention to the operation in question. In some cases, but very rare ones, the operation was to be performed: he had seen patients who had died from the effects of the profuse suppuration solely; no disease could be found in the internal organs. He thought that most cases of the disease commenced as synovitis, and not from scrofulous deposit in the head of the bone, which latter cause of disease he looked upon as unfrequent.

Mr. COULSON was of opinion that hip disease was generally of a scrofulous origin, and as amenable to constitutional treatment; that the operation should be put in force at the last stage of the disease, when all hope of recovery by other means was given up; that the constitutional disturbance was not due to the local malady, but both had the same origin.

He stated that four post-mortems at the Margate Infirmary had shown the acetabulum to be extensively diseased. In respect of the cases brought forward by Mr. H. Walton, he thought the operation should not have been performed in many of them.

SURGICAL SOCIETY OF PARIS.

Dec. 4, 1850.

Osteosarcoma on the Upper Extremity—Amputation—Cure.

M. H. LARREY, on behalf of M. Lâcome, of Argelès, exhibited a cast of an arm on which was situated an enormous osteosarcoma. The limb was amputated about four years ago, since which time the man had enjoyed perfect health. The arm, without the forearm, had weighed twenty-three pounds; its circumference at its widest part measured sixty centimetres (= 23·62 Eng. inches).

ACADEMY OF SCIENCES, PARIS.

Dec. 2, 1850.

Repeated Injections of Iodine in the Treatment of Encysted Tumors.

M. BORELLI, of Turin, transmitted a work on this subject, in which he stated his practice. M. Borelli makes a small oblique opening into the cyst, by which he evacuates its contents. He then injects, by means of a syringe, an alcoholic solution of iodine, which he leaves in the cyst, closing the aperture with diachylon or charpie. Pain ensues in the course of two or three minutes, and continues for about twenty-four hours. The inflammation which is excited may usually be allayed by a poultice. The tumor which before was tense and painful becomes softened and diminished in size, while a coloured fluid oozes from the incision. Sometimes, after the first injection, and as soon as the local inflammation has subsided, the cyst becomes detached, and may be extracted from the tumor with the forceps; but usually it is necessary to repeat the injections two or three times before obtaining a complete separation. When the cyst is withdrawn, the radical cure is easily completed.

A Particular Appearance of the Uterus during Menstruation.

M. RIPAULT, of Dijon, stated that he had observed that for a few days before menstruation one or two veins on the anterior surface of the neck of the uterus became enlarged or varicose; that towards the end of the menstrual period they decrease in size, while other veins appear enlarged on the posterior lip; and that with the cessation of the catamenia these appearances altogether subside.

On the Action of Salts of Silver.

M. DELIOLUX, of Rochefort, proposed that, to prevent the discolouration of the skin by nitrate of silver, it should be administered in combination with the iodide; and that to obviate topical irritation the salts of silver should be given in albuminous fluids, with alkaline chlorides, which facilitate their absorption.

On the Treatment of Scabies.

M. BOURGUIGNON transmitted a letter in which he answered the charges of M. Bazin.

Correspondence.

THE CENSUS OF 1851 IN RELATION TO PUBLIC AND PRIVATE LUNATIC ASYLUMS.

SIR,—As the subjoined correspondence between myself and the Registrar-General will be read with interest by a large class of professional gentlemen associated with public and private Lunatic Asylums, I offer no apology for transmitting it to you for publication in your journal.

It certainly would have been most unjustifiably inquisitorial if the proprietors of private asylums for the insane had been compelled to make a return of the names of the patients placed in confidence under their care.—I remain, sir,

Your obedient servant,
FORBES WINSLOW.

Dec. 9th, 1850.

To the Registrar-General.

SIR,—I perceive by the printed form of the Census for 1851, issued, I believe, under your authority, that it will be necessary for each householder to make, agreeably to a prescribed tabular form, an accurate return of the christian and surname, age, occupation in life, &c., of each person sleeping under his roof on a specified night.

As I am much interested in behalf of a numerous and influential section of the medical profession, viz., those engaged in the care and treatment of the insane, may I be permitted to ask whether the resident proprietors or medical superintendents of private and public asylums will be required to make a return of the names of patients placed under their care, and actually resident with them at the period when it is proposed to take the census? Your early attention to this matter will much oblige, sir,

Your obedient servant,
FORBES WINSLOW, M.D.

Albemarle Street, Dec. 5th, 1850.

Census Office, Craig's Court,
Dec. 7, 1850.

SIR,—In reply to your letter of the 5th inst., I have to state that I should think that, rather than return the names of all patients in Lunatic Asylums, it may be sufficient if the initials of their names be recorded when the Census of 1851 is taken, to which I should think there would be no objection.—I have the honour to be, sir,

Your faithful servant,
GEORGE GRAHAM, Registrar-General.
Dr. Forbes Winslow, M.D.

**FEES FROM INSURANCE OFFICES.—THE
STANDARD LIFE ASSURANCE OFFICE.**

SIR,—If it were a personal matter I should not trespass on your space by a reply to Mr. J. R. Fisher's letter, but as the interests of the profession are involved I must needs do so.

Without admitting for one moment Mr. Fisher's explanation of his reason for paying me my fee, or the ingenious turn he has given to his motive for so doing, in requesting me to recommend their office on condition that my fees should be paid, I shall not offer any refutation of the one or explanation of the other, because his admission that he paid a "brother practitioner" a fee when he had not any *charitable motive* for doing so, is sufficient for my argument, "that the Standard Office will pay when sufficiently pressed;" and this position is corroborated by what happened since the letter of which this is a copy was written,—namely, another "Brother Practitioner" (having seen my former letter) told me that he had lately received a fee from the agent of the Standard in a neighbouring town.

It matters little, I presume, to the profession, whether the agent or the office pays the fee (and they will judge for themselves who does,) so that they get it; but to my mind Mr. Fisher has done little for the honour of the Standard Office by his *virtual* admission, that he is so liberally paid that he can afford from his salary or commission rather to pay medical fees or dispense charitable donations, whilst the just demands of the profession are withheld by the Company.

However, the matter is virtually settled; with the Royal Exchange at the head of nearly fifty "paying Offices," the result cannot be doubtful; and if the profession will only be true to itself, which it will, we shall soon have the Standard Office in self-defence not only a *paying*, but a "*recognised paying*" office.

Your obedient servant,

J. H. HOUGHTON.

Dec. 1850.

OBITUARY.

On the 12th inst. at Camden New Town, Robert Calvert, M.D., Deputy-Inspector of Military Hospitals, aged 68.

On the 28th ult., on board the bark Clara, off the Island of St. George, Azores, John Garnett Courtenay, Esq., Staff Surgeon, late principal medical officer of New Zealand.

On the 11th inst., at Uxbridge, in the 70th year of his age, Richard Andrews, Esq., many years surgeon at Great Stanmore, Middlesex, much respected by all who knew him.

Medical Intelligence.

UNIVERSITY OF LONDON.

M.D. EXAMINATION—1850.

Examination for Honours.

Monday, Dec. 25.—Afternoon, 3 to 6.

*Commentary on a Case in Medicina. Cal-
sus de re Medica.*

Examiners, Dr. BILLING and Dr. TWINKLER.

R. W. *et.* 28, when first visited on the 20th of December, stated that he generally enjoyed good health, that his present indisposition, which was of three weeks' duration, and had been preceded for ten or twelve days by slight cough, commenced by severe headache, loss of appetite, thirst, and chilliness succeeded by hot skin and tendency to sweating. The chilliness, which recurred every day at the same hour during the first week, had entirely disappeared. The bowels were at first confined, but for the last few days he had felt gripping pains in the abdomen, accompanied by frequent liquid evacuations from the bowels, and on the previous day he had voided by stool about half a pint of dark-coloured blood.

On the 21st he complained of epigastric tenderness and urgent thirst. The tongue was clean at the edges, brownish in the centre; but there was no headache and no pain of limbs; the pulse was only 76. There was little cough, the respiration was easy, the chest clear and resonant on percussion, and no kind of râle accompanied the respiratory murmur. His manner was calm, and, though he replied to questions rather slowly, his intelligence was unimpaired. In the evening there were slight chills, followed by heat of skin, but no sweating. The accession returned on the next and following days, but a little sooner. On the 25th there was no chill, but the diarrhoea, which had ceased since he was first visited, reappeared, and he had passed fifteen liquid stools. By the remedies administered it was again restrained, though in the next few days it was evident that his powers were much depressed.

On the 1st of January he had frequent bilious vomiting, and passed from eight to ten small liquid dejections. Next day the expression of his countenance was visibly altered, the speech more slow, the pulse quicker, the skin moderately hot: there was cough accompanied with slight mucous expectoration. He had passed only three evacuations from the bowels during the day.

During the night of the 3d and 4th he

suddenly experienced very severe pain in the hypogastrium, so severe as to cause him to utter loud shrieks; it continued with undiminished severity for an hour, and then abated considerably. When visited on the following day the belly was soft, and could be examined without apparently inducing any pain. The features, however, were much contracted, and his general powers very feeble: the pulse 110, respiration frequent, tongue clammy, and he complained of much thirst. On the morning of the 5th his countenance had become more animated, the whole body was covered with a profuse sweat, the abdomen was slightly tender, the tongue white, but his thirst had abated, and he had passed no stool for 24 hours. This apparently calm state was, however, interrupted in the evening by bilious vomiting. In the course of a few hours he complained of feeling very ill, and expired before midnight.

What was the nature of this disease?

What appearances would you expect to find on examination of the body after death?

How would you have treated this disease?

Translate:—

Ubi verò febris aliquem occupavit, scire licet non periclitari, si in latus aut dextrum aut sinistrum, ut ipsi visum est, cubat, cruribus paulùm reductis; qui ferè sani quoque jacentis habitus est; si facillè convertitur, si noctè dormit, interdum vigilat, si ex facili spirat, si non conflictatur; si circa umbilicum et pubem cutis plena est: si præcordia ejus sine ullo sensu doloris æqualiter mollia in utràque parte sunt. Quòd si paulò tumidiore sunt, sed tamen digitis cedunt et non dolent, hæc valetudo, ut spatium aliquod habeat, sic tuta erit. Corpus quoque, quod æqualiter molle et calidum est, quodque æqualiter totum insudet, et cujus febricula eo sudore finitur, securitatem pollicetur. Sternutamentum etiam inter bona indicia est; si cupiditas cibi vel à primo servata, vel etiam post fastidium orta. Neque terrere debet ea febris quæ eodem die finita est; ac ne ea quicquam, quamvis longiore tempore evanuit, tamen ante alteram accessiorem ex toto quievit, sic ut corpus integrum, quod *εισπρηγνύς* Græci vocant, fieret. Si quis autem incidit vomitus, mixtus esse et bile et pituita debet, et in urinâ subsidere album, læve, æquale; sic ut etiam, si quæ quasi nubeculæ innatarint, in imum deferantur; at venter ei qui à periculo tutus est, reddit mollia, figurata, atque eodem ferè tempore quo secundâ valetudine assuevit, modo convenientia his quæ assumentur.

Pejor cita alvus est: sed ne hæc quidem

terrere protinus debet, si matutinis temporibus coacta magis est, aut si, procedente tempore, paulatim contrahitur et rufa est, neque fœditate odoris similem alvum sani hominis excedit. Ac lumbricos quoque aliquos sub finem morbi descendisse nihil nocet. Si inflatio in superioribus partibus dolorem tumoremque facit, bonum signum est sonus ventris inde ad inferiores partes evolutus; magisque etiam si sine difficultate cum stercore exeat.

Case in Midwifery.

Examiner, Dr. RIGBY.

Mrs. B., ætat. 42, mother of ten children.

July 18, 1850, eight months pregnant.

The membranes broke this morning, and there has been more or less discharge of blood; she was at a party last night, and was much oppressed by the heat of the weather; moreover, she slipped down two or three days ago: her bowels have been confined and unhealthy; they have been but partially rectified by medicine; the liver is torpid, and the tongue fissured.

Examination per vaginam.—The vagina is full of clots; the os uteri, which can barely be reached with the finger, is just beginning to dilate: no presenting part can be reached: liquor amnii dribbles away: occasionally she has a slight pain, which increases the discharge.

July 19.—Slept well, had occasional slight pains all day; at about 6 P.M. they increased, and a hand could just be reached, the os uteri being about two-thirds dilated: both it and the os externum were very dilatable, and the attendant passed his hand with great ease: the other hand of the fœtus was found close by that which presented, but it was so soft and pliable that he did not feel certain until he had reached the elbow. On passing towards the abdomen of the child, he found the legs, and brought one down: there was no pulsation in the cord, which passed between the child's legs. When the foot was brought into the vagina, it was left there until pains should come on. In half an hour they returned; more liquor amnii and blood followed; then came the nates of the child with the other foot; the arms, shoulders, and head followed with great ease: the child was dead: there was some hæmorrhage afterwards, which was stopped by ergot, cold, and pressure.

The candidate is requested to make a few remarks on every practical point which may strike him.

Case of Surgery for Commentary.

Examiners, Sir STEPHEN HAMMICK and Mr. HODGSON.

A gentleman, 65 years of age, of robust

stature, but apparently of a phlegmatic temperament, of active habits, moderate in the use of fermented liquors, but addicted to much and good eating, rubbed the skin off the first joint of the left second little toe by wearing a tight boot. He suffered but little inconvenience for a week, when the toe became excessively painful and slightly inflamed. He thought he had an attack of gout; but he had never suffered from that disease, nor had he any other symptoms of it. In the third week from the time of the injury, the pain having continued unabated, the toe became dry, black, and in a gangrenous state, to its metatarsal joint. The pain then ceased, and only a very slight degree of inflammation was observable over the metatarsus. The pulse at the wrist and the movements of the heart were feeble, but no unnatural sound could be detected in the precordial region. In the sixth week the inflammation extended over the metatarsus, accompanied with acute burning deep-seated pain in the foot generally, increased feebleness in the pulse at the wrist and at the heart, dry brown tongue, loss of appetite, and great prostration. In the seventh week gangrenous patches formed on the upper part and on the sole of the foot, preceded by slight swelling and vesications. The gangrenous patches extended, and in the eighth week reached to the ankle, having become partially detached in some places from which offensive putrid matter and sloughs were removed. The powers of the system gradually declined, low delirium and subsequently coma came on, and the patient died at the end of the eighth week from the time when he first perceived the abrasion of the toe.

In commenting on this case you are requested to describe the different forms of gangrene and their causes, symptoms and pathology, both with reference to remote organs and the state of the parts in which those conditions exist. You will also mention the modes of treatment, both general and local, which you would adopt, with your reasons for their employment.

Tuesday, November 26—Morning, 10 to 1.

Medicine.

Examiners, Dr. BILLING and Dr. TWEEDIE.

1. Explain the general principles on which the treatment of dropsy is founded.
2. Describe the different forms of small-pox. Sketch the symptoms, progress, and treatment of confluent small-pox.
3. Explain how pneumo-thorax may arise. Give its physical signs and treatment.
4. Describe the anatomical characters, diagnostic symptoms, and treatment of acute hydrocephalus.

Afternoon, 3 to 6.

Medicine.

Examiners, Dr. BILLING and Dr. TWEEDIE.

1. Describe briefly the conditions of the heart (organic and functional) which are accompanied by abnormal sounds.
2. Enumerate the principal varieties in the expectoration in pulmonary diseases. What are the diagnostic indications to be drawn from each?
3. Sketch the causes, nature, and treatment of anaemia.
4. Describe the anatomical characters, diagnostic symptoms, and treatment of laryngitis.

EXAMINATIONS FOR THE FELLOWSHIP AT THE ROYAL COLLEGE OF SURGEONS.

THE following questions on *Anatomy* and *Physiology*, in addition to those published in our last number, were submitted to the four Candidates:—

1. Describe the minute structure of bone.
2. Describe the apparatus for the excretion of the bile, the composition of the fluid, and the purposes in the economy of this secretion.
3. Describe the ganglia, connected with the three divisions of the fifth cerebral nerve; their size, situations, their roots and offsets.
4. Describe how you would expose the trunk of the internal maxillary artery; its course, relative position, and branches.
5. Describe the disposition of the pelvic fascia in the male.
6. Describe the structure of muscle, explaining the difference between the muscular fibre of organic life and that of animal life.

The following were submitted in *Pathology* and *Surgery*—viz.,

1. Describe the injuries which occur at the shoulder-joint, and how they are to be distinguished from each other.
2. Describe the swellings met with in the groin, and how they are to be distinguished from each other.
3. In what forms of secondary syphilis is the use of mercury advisable? Describe the modes of administering this remedy, indicating that which is to be preferred, and the precautions requisite during a mercurial course.
4. Under what circumstance and to what joints is excision of the articulating extremities applicable? What objections may be taken to this operation?
5. When, in operating for strangulated hernia, the bowel is found in a state of mortification, partially or wholly, what treatment is to be adopted, and how does

recovery take place under these circumstances?

6. Describe the operation for the removal of stone from the urinary bladder by lithotripsy, the cases to which it is adapted, and those to which it is not.

OPERATION FOR CATARACT ON A GRIZZLY BEAR. BY MR. GUTHRIE.

THE patient having been separated from the other bears, a strong leathern collar and chain was buckled round his neck, and the chain being passed round one of the front bars of the cage, two strong men proceeded to pull him to it as a bullock is hauled to the slaughtering ring. The bear was the size of a young donkey, and his resistance was quite remarkable; for full ten minutes he set their efforts at defiance, and ultimately it was only by the united strength of four men that he was placed in a position favourable for the application of chloroform. Dr. Snow endeavoured to hold a sponge to his nose, but it was only by fairly tying it to his muzzle that the object was attained. The dropping of the paws, with the cessation of his roarings and struggles, told that he was insensible; and the sponge being removed, he was laid with his head on a plank outside the den. A solution of atropine had been placed in the eyes on the previous evening, and the pupils were found fully dilated. The instrument used was a strong straight cutting needle. The extraordinary toughness and thickness of the cornea rendered the insertion of this difficult; and the lens was singularly large in proportion to the eye. This rendered the breaking up of that body by no means easy, and it occupied full a minute. The morning was dark, and the margin of the deep brown iris not distinctly seen, which led to its being wounded in one eye and bleeding freely. The cataracts having been thoroughly destroyed, the bear was drawn again into the den. For some minutes he remained in a state of profound coma, giving scarcely any evidence of life, but gradually recovered, and rising with some difficulty he staggered into his sleeping apartment.

On my going to his den the following morning the door of the dormitory was thrown open, and to my surprise he came out with his eyes open, faced the light without the slightest inconvenience, and began licking his paws with perfect satisfaction. A dose of Rochelle salts was given to him rather as a matter of precaution than because they were needed, and his recovery was rapid, not one red vessel discolouring the conjunctiva at any time.

MEDICAL WITNESSES AT THE CENTRAL CRIMINAL COURT.

ACCORDING to an order just issued, medi-

cal men bound by recognizance or subpoenaed and attending professionally, to be allowed one guinea per day, and no more.

No witness to be allowed for his attendance before a committing magistrate, except by the certificate of such magistrate. No witness to be allowed his expenses upon more than one prosecution on any one day, although he may be a witness on several, unless for his attendance before a committing magistrate.

MEDICAL APPOINTMENTS.

MR. ERASMUS WILSON has been appointed chairman of the sectional committee for the exhibition of surgical instruments at the forthcoming display of the industry of all nations. Dr. Stevenson Bushman has been elected senior physician to the Metropolitan Free Hospital. Mr. R. A. Stafford has been appointed by the Council of the Royal College of Surgeons to deliver the annual oration in memory of John Hunter, for the year, 1851.

APOTHECARIES' HALL.

NAMES of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, 12th December, 1850:—William Morse Graily Hewitt, Badbury, Swindon, Wilts—Henry Penfold, Brighton—John Chamberlayne Barry, Draycot, Chippenham, Wilts—James Jeken, Dover—Lucius Warrillow, Birmingham—Albert Fleming—Samuel Morris, Colchester—Henry Manley, Crediton, Devon—Thomas Henry Stocker Pullin, Sidmouth, Devon.

The registration of the medical students attending the metropolitan schools has been conducted at Apothecaries' Hall.

1116 students have been registered for the medical session 1850-51,—the largest number since the session 1842-43. Of these 371 are new students.

AN ACCOUNT OF A RECENT EPIDEMIC OF SCARLATINA IN BERLIN.

DR. HELFFT states that the scarlatina which has lately prevailed epidemically in Prussia, and other parts of Germany, has presented several anomalous features, which he deems it his duty to lay before the profession.

In many cases all the symptoms of scarlatina except the eruption were noticed in members of the same families among whom the fully developed disease was present.

In very many patients the disease assumed a malignant character; and here the surface was pale, or the skin presented a dark purple colour, and in others was studded with petechia. In these cases the temperature of the surface

of the body was much lower than natural. The pulse was small, frequent, and sometimes intermittent. The fauces were of a dark red colour. The tonsils presented deep ulcerations, by which they were partially or totally destroyed. Diphtheritis was frequently observed, spreading over the upper part of the pharynx and the fauces, extending to the Eustachian tube and the posterior nares, and accompanied by a copious, acrid and fetid discharge from the mouth and nostrils. The tongue, at first of a dark red colour, its papillæ enlarged, soon became covered with black sordes, which also coated the lips. The lymphatic glands in various regions of the body were swollen and inflamed; those of the neck were swollen in every case; and sometimes the inflammation of these glands proceeded to suppuration and wide-spreading ulceration, extending into the pharynx and adjoining parts. Inflammation of the conjunctiva, with ulceration of the cornea, was noticed in some cases. Œdema of the integuments and effusion into the cavities was seldom met with. In one case hæmorrhage from the nose, mouth, and intestinal canal occurred; and in all the worst cases the evacuations were of a black or dark green colour. The urinary secretion was suppressed in the beginning of almost every case; towards the close, however, it passed involuntarily. In one case, in which after death distinct degeneration of the kidneys was found, no albumen could be detected in the pale and copious urine: its sp. gr. was 1010.

The kidneys in almost every case were found enlarged, or acutely inflamed; but the granular or Bright's disease was not observed. The liver was paler than natural. In one case the spleen was observed of a yellowish colour, and infiltrated with pus. In another case, attended with swelling of the upper extremities, the glands of the axilla were found enlarged and containing pus. The lungs were free from disease. The pleura presented ecchymoses. Various pathological changes were found in the intestinal canal, *e. g.*, softening of the mucous membrane, ulcerations of the mucous membrane of the ileum, paleness of the membrane in other portions of the intestines. In most cases the ileum and colon were of a dark colour, varying through several shades from green to deep black.

The treatment, at first of a tonic character, was not successful; a change to small doses of calomel, as advised by some English authors, was found very serviceable. Subsequently, when hæmorrhages occurred, bark and acids were employed. Nitrate of silver was applied to the local diseases. — *Zeitschrift für die Gesamte Medicin.* X

BIRTHS & DEATHS IN THE METROPOLIS

During the Week ending Saturday, Dec. 14.

BIRTHS.		DEATHS.	
Males....	728	Males....	543
Females..	706	Females..	567
	<hr/> 1434		<hr/> 1090

CAUSES OF DEATH.

ALL CAUSES	1869
SPECIFIED CAUSES	1869
1. <i>Zymotic</i> (or Epidemic, Endemic, Contagious) Diseases	280
<i>Febrile Diseases, viz.—</i>	
1. Dropsy, Cancer, &c.	46
2. Brain, Spinal Marrow, Nerves, and Senses	149
3. Heart and Bloodvessels	46
4. Lungs and organs of Respiration	271
5. Stomach, Liver, &c.	46
6. Diseases of the Kidneys, &c.	17
7. Childbirth, Diseases of Uterus, &c.	12
8. Rheumatism, Diseases of Bones, Joints, &c.	6
9. Skin	10
10. Premature Birth	30
11. Old Age	45
12. Sudden Deaths	7
13. Violence, Privation, Cold, &c.	27

The following is a selection of the numbers of Deaths from the most important special causes:

Small-pox	24	Convulsions	40
Measles	20	Bronchitis	112
Scarlatina	20	Pneumonia	112
Hooing-cough	42	Phthisis	116
Diarrhoea	10	Lungs	14
Cholera	3	Teething	7
Typhus	37	Stomach	5
Dropsy	17	Liver	9
Hydrocephalus	21	Childbirth	7
Apoplexy	20	Uterus	3
Paralysis	20		

REMARKS.—The total number of deaths was 76 below the average mortality of the 50th week of ten previous years.

METEOROLOGICAL SUMMARY.

Mean Height of the Barometer	29.93
Thermometer	40.1

* From 12 observations daily. * Sum.

RAIN, in inches, '43.—Sum of the daily observations taken at 9 o'clock.

METEOROLOGICAL.—The mean temperature of the week was about the mean of the month.

NOTICES TO CORRESPONDENTS.

We have been compelled to postpone the papers of Dr. Pollock, Dr. Griffith, and Mr. Galloway, as well as the report of the Liverpool Society and other articles, which are in type.

J. M. M., Edinburgh.—We regret that it is not in our power to furnish any other reference than that already given.

We are obliged to the Rev. J. Barlow for the admission ticket.

We thank Mr. H. Janson for his letter and advice. Our opinions of Mesmerism continue unchanged.

REMARKS UPON THE
CRYSTALS OF OXALATE OF LIME
OCCURRING IN THE URINE.

By J. W. GRIFFITH, M.D., F.L.S.

Member of the Royal College of Physicians, and
Physician to the Finsbury Dispensary.

THE crystals of the oxalate of lime belong to the two and one axial or square prismatic system,* and not the cubic or tesseral. The knowledge of this fact enables us to explain the production of the colours, cross, and rings frequently seen on subjecting its various forms to the action of polarised light. The octohedra of the oxalate of lime do not exhibit the phenomena of depolarisation to any extent unless they are large: when so, and especially when united at their edges, as we not infrequently find them, they exhibit the usual colours. Other varieties of oxalate of lime are not infrequently met with, some of which are of a flattened ellipsoidal form, depolarizing light beautifully; others, again, are of this form, but constricted in the middle. The latter have been denominated dumb-bell crystals. These three principal forms, and numerous intermediate varieties, are, as I have stated in my Manual, of the same composition, and exhibit all the chemical characters of oxalate of lime; and they may be prepared artificially from chemically pure oxalate of lime; but, if proper care be not used in washing, and other details of preparation, prior to the application of reagents, all accuracy of investigation, and all certainty, vanish.

I believe that inattention to one or two of such points has led to the adoption of the erroneous idea that the dumb-bell forms of crystal not infrequently met with in the urine consist of oxalurate of lime. There can be no question that this view is totally untenable. The oxalurate of lime is a

somewhat troublesome salt to prepare on account of its solubility in water whereas the oxalate of lime is wholly insoluble in this menstruum. In the statements communicated to the MEDICAL GAZETTE for Oct. 25th, 1850, with a view to show that these dumb-bell crystals consist of oxalurate of lime, there is an evident source of fallacy. Thus we are told that, when they were kept under water, at a temperature of 85°—90°, for ten days, in a greenhouse, the water in which they were immersed became turbid, and evolved a fetid ammoniacal odour. Now I certainly have never made the experiment under such circumstances, but I should have no doubt that, if pure oxalurate of lime were decomposable or decomposed in this manner, the products would be oxalate of lime and oxalate of urea, which substances would require more than a lapse of ten days at this temperature to undergo further decomposition. From no other cause, however, could any fœtor accompany the ammonia evolved than the admixture of some foreign organic matter: this, in the case alluded to, was undoubtedly some remains of the urine from which the crystals had been obtained: hence also the cause of the crystallization of the muriate of ammonia in cubes, granting that the cubes were not chloride of sodium.

Oxalurate of lime has not hitherto been shown to assume the form of the dumb-bell. I have, however, sometimes artificially obtained the prisms of this salt aggregated into a somewhat similar shape, which is not unfrequently met with in the case of many other crystalline compounds; but in the instance of the oxalurate, the crystals of which they consisted have been larger, and more resembling the aigrettes of uric acid than the fine needles of which the dumb-bells of the oxalate consist.

The oxalate of lime is, however, readily obtained in the dumb-bell form by dissolving recently precipitated, chemically pure oxalate of lime in nitric acid, and evaporating the solution rather rapidly. These crystals exhibit the form in perfection, yielding the cross and rings with polarised light. It is quite clear that in this case they cannot possibly contain anything more than oxalic acid, lime, nitric acid, and water. They do not contain any nitric acid, as I have ascertained by

* This is the opinion of M. Schmidt, who has examined the point carefully. I should, however, be inclined to regard the oxalate of lime as belonging to the right prismatic, or 1 and 1 axial system; for the base of the common octohedron is frequently rectangular, and oxalate of lime is easily obtained in the form of flat rhombic plates. M. Schmidt appears to regard the latter as composed of a hydrated salt; but, from the consideration of some circumstances under which I have obtained it, this view does not appear probable. There can, however, be no question that oxalate of lime does not belong to the cubic system.

carefully testing them. When dried at a temperature beginning at 212° , and ceasing at 266° F., they were unchanged in every respect: they exhibit all the chemical characters of the dumb-bell crystals, and of chemical pure oxalate of lime. The only remaining consideration, then, in regard to them is, whether they contain hydrate water: although the fact that no change was produced in them by the elevated temperature to which they were exposed would render this view improbable, yet, as the accurate determination of this point was foreign to the object of the present paper, I have not at present carried the investigation further. It is, however, a common occurrence for an insoluble salt containing no water, when crystallized from an acid solution, to separate in a hydrated form.

Again, the dumb-bell crystals found in urine re-crystallize in the same form from a nitric solution. I have not been able to obtain this result with the oxalurate of lime, although, as already stated, I have with the oxalate. I believe the oxalurate of lime is decomposed by boiling nitric acid. Moreover, when the dumb-bell crystals of oxalate of lime are heated to redness, the remaining mass retains its primitive form, which is not the case with the oxalurate: this fuses, and forms an irregular porous mass, from the union of adjacent crystals in a state of fusion, spaces unoccupied by portions of the substance being left vacant.

I have made many other experiments upon the crystallization of oxalate of lime from various acid solutions, with interesting results; but, as they do not refer to the present paper, I shall omit any account of them.

The dumb-bell crystals of the oxalate of lime, as also those of the oxalate of soda, consist of aggregations of minute needles radiating from a centre: in some cases these prisms may be distinctly seen projecting beyond the general outline formed by the others.

THE MEDICAL SCHOOLS OF CANADA.

WE understand that the following numbers represent approximately the students in attendance at the various medical schools in Canada:—Toronto—King's College, 35; Upper Canada School of Medicine, 10; Dr. Rolph's school, 25. Montreal—McGill College, 47; School of Medicine, 23. Quebec—School of Medicine, 20.—Total, 160.

A CASE OF PORTAL PHLEBITIS, AND CASES OF JAUNDICE.

BY W. B. KESTEVEN, M.R.C.S.

Jaundice—Ascites—Death—Coagula and Pus in the Portal, Splenic, Mesenteric, and Pancreatic Veins—Pathology of the Case—Other Cases of Jaundice—Hæmorrhage from the Bowels.

As carefully recorded cases constitute the *materiel* of medical reasoning, it clearly the duty of practitioners to bring forward such as appear to them to possess features of interest or importance. This circumstance, together with the obscurity which frequently attends the diagnosis of hepatic derangement and chronic structural disease of the liver, and the peculiarities of the following cases, may, it is hoped, sufficiently apologise for their publication, with their accompanying remarks. Besides these reasons, the writer has thought that the case first to be related might be permitted to stand in the relationship of companion to a case of Uterine Phlebitis lately published in the MEDICAL GAZETTE,* with the pathology of which it presents points of resemblance and of contrast. Both cases have the same essential pathological character in consisting of inflammation of veins, while they respectively illustrate the wide difference that may be exhibited by the symptoms and course of diseases arising out of causes essentially similar in their nature.

Inflammation of the portal system of veins is a somewhat rare occurrence. The writer has examined the works of the best English pathologists and systematic authors on medicine that he has at hand, and finds mention of one instance only of a like character, by Dr. Copland. The records of the Pathological Society of London do not supply a parallel case.† In Hasse's Pathological Anatomy,‡ however, he learns that it has been observed more frequently among our Continental neighbours—e.g. twice by Bouillaud, twice by Rehard, once by Dance, once by Belling, twice by Schönbein, once by

* November 30th.

† See LONDON MEDICAL GAZETTE, *passim*.

‡ Published by the Sydenham Society.

Mohr, and once by Hasse himself. The symptoms assigned to this form of disease by Hasse are, briefly, emaciation, ascites, diarrhoea, &c., being nearly the same as noticed in the following imperfect history:—

The writer must here premise that the patient was admitted into St. Bartholomew's Hospital, under the care of Dr. Latham, in the year 1836, at which time the writer was clinical clerk to Dr. Latham. He has had the notes of the post-mortem examination which he then took in his possession since that period and he makes his present report of them by permission of that physician, his highly-esteemed preceptor in *rebus medicis*.

CASE.—M. B., aged thirty-two years, in a jaundiced state, and suffering under ascites, with what was regarded as Peritonitis. All that could be learnt of her history was, that she had been an inveterate spirit-drinker, that she had been jaundiced four months, and that she had had quotidian ague seven months before admission into the hospital. Her end was, that she died comatose a few days afterwards.

Post-mortem examination.—The body was much emaciated: every tissue and organ in the body was tinged with bile. Sero-sanguineous effusion was found in the sac of the arachnoid covering the upper surface of the hemispheres of the brain. On the right side, a thin coagulum covered the convolutions on the superior aspect of the cerebrum. The thoracic organs were all healthy. The abdominal cavity contained several quarts of serous fluid of a deep yellow colour. The peritoneum exhibited no appearance of inflammatory action. The liver was somewhat enlarged, and presented externally a deep red colour, and was studded with small whitish specks, varying in size from that of a pin's head to that of a sweet pea. The latter were much more abundant on the upper than on the lower surface of the liver. On making an incision into the substance of this organ, pus exuded at numerous points, corresponding for the most part with the orifices of portal veins. The gall-bladder was distended with secretion from its mucous membrane, tinged of a yellowish colour, but contained no bile. A few biliary concretions were found within it. The ducts leading to and from the gall-bladder were rendered

imperforate by an indurated state of the areolar tissue where the ducts join, and along their course to the intestine.

The spleen was enlarged and somewhat indurated in its texture. The pancreas was apparently healthy, but tinged of a deep yellow hue. The splenic and mesenteric veins in their chief trunks, with their junction at the portal vein, were filled with pus, which extended throughout the ramifications of this vein in the substance of the liver, and exuded from their orifices when divided. The veins proceeding immediately from the spleen and mesentery did not contain pus, while the primitive branches of the pancreatic veins were found to convey this fluid. Coagula of blood were found in the pancreatic veins, as also in the splenic and mesenteric veins. These coagula were adherent to the inner surface of the vein, or rather to a yellow fibrinous deposit which lined these vessels, as far as the liver, and in the opposite direction as far as the small omentum. The deep yellow colour of this fibrinous deposit was doubtless attributable to the bile which had pervaded and discoloured every tissue in the body. No pus was found in any other veins that were examined.

At a spot about the middle of the course of the trunk of the portal vein, one large coagulum of blood seemed almost to have closed the calibre of the vessel. When cut into, this coagulum presented a laminated appearance, each layer becoming more devoid of red globules, and less dense, until in the centre was found what resembled a small quantity of pus. The other smaller coagula were likewise covered with a deposit of lymph. The internal living membrane of the veins presented in some parts a reddish tinge, especially where the coagula were adherent. Corresponding to these internal adhesions, the outer cellular tissue was thickened, and adherent to the vessel. In some of the smaller portal veins phlebolites were also discovered.

The stomach and intestines presented numerous patches of congestion. All other organs were healthy.

REMARKS.—There can be no room for reasonable doubt that the jaundice, ascites, and death here recorded, were attributable to the obstruction offered to the portal circulation by the presence of the

coagula and pus contained in the portal veins. The source of these products could only have been inflammation of those veins producing the formation of pus at some one or more points, and the subsequent inevitable coagulation of the blood around the globules of pus, which it has been shown by Mr. Lee, in his recently published Jacksonian Prize Essay, it is the property of pus to produce, when mixed with blood, either in or out of the vessels. The coagulum thus formed would become adherent to the first surface with which it came in contact, in the mesenteric, splenic, pancreatic, and portal veins. But clearly as this may appear, after the microscopical examination, the true nature of the disease would doubtless have remained hidden during life, had it lasted even a much longer period. All the symptoms that were observed might have been referred by the most competent authorities to several different pathological conditions, and to each or either of them with great show of probability. Thus they might have been with justice assigned to chronic inflammation of the liver, to simple chronic congestion of the portal system, to chronic degeneration of the hepatic structure, to disease of the gall-bladder or ducts, or their obstruction, to chronic disease of the spleen, or lastly, to disease of the mucous membrane of the duodenum preventing the discharge of bile from the common bile-duct. One or all of these forms of disease being familiar to the practitioner, in connection with the same set of symptoms, it is possible that the real pathological conditions, as revealed on dissection, might not have been conjectured by any who witnessed the case during life.

The readiness with which veins take on the inflammatory process is well known, and is often too well exemplified in the puerperal state. The processes by which obstruction of the vein takes place were not so well known to the profession until the publication of Mr. Lee's experimental researches, by which it is shown that the coagulation of the blood in the veins is a secondary consequence of their inflammation, while the adhesion of the coagulum is an occurrence quite independent of inflammation, although inflammation may subsequently result, and lymph be secreted as its effect, the obstruction having

caused increased action of the internal surface of the vessel, by reason of the impediment offered to the circulation detaining irritating matter in contact with its surface.

The existence of inflammation and pus in so large an extent of the portal venous system as was here divulged by dissection could not have been so long tolerated by the system unless the blood had been slowly undergoing such morbid changes, under the influence of the depraved habits of the patient, that its coagulability, which it is obvious existed at some period of the progress of the case in its integrity, had become so far impaired as to admit the circulation of a very large admixture of pus with itself throughout an extensive district of the vascular system. At what period, or even to what extent, this alteration may have taken place, the history of the case furnishes no data for determination. It may be stated as more than a mere conjecture that the large coagulum found in the trunk of the portal vein was the first to attach itself to the surface of the vessel, and offer obstruction to the circulation. A retrograde circulation would then ensue, throwing blood containing pus globules, the result of inflammatory action excited by the presence of the coagulum, back into the splenic, mesenteric, and pancreatic veins, where coagula were found adherent at several points.

The subsequent dilatation of the portal vein and contraction of the coagulum permitted the transmission and universal diffusion of pus through the portal system which was observed to have obtained when incision was made in the course of those vessels in the substance of the liver, and which had proceeded to the formation on its upper surface of numerous small abscesses in its parenchyma.

Although in such a case the circulation may be carried on by anastomosis, yet it is clear that such diversion was not sufficient to relieve the abdominal circulation otherwise than by serous effusion—ascites. It is also equally clear that the state of the portal circulation did not entirely prevent the secretion of bile, from the fact of its having been found to have pervaded tissue in the body, its entrance into the gall-bladder having been prevented by the effects of chronic inflammation external to the ducts, by which their cavities

were obstructed.* M. Raikew mentions cases in which complete closure of the portal vein, from the presence of pus or coagula, as well as from chronic thickening and contraction of the vessel, were found to coexist with abundant secretion of bile.

Mr. Abernethy† inferred that the hepatic artery was sufficient for the supply of blood requisite to the secretion of bile, from having found the portal vein opening into the inferior *cava* near the emulgent veins, notwithstanding which bile was poured into the intestines and filled the gall-bladder. Mr. Lawrence‡ has also related a similar case. The same fact has been ascertained experimentally by several experimentalists, who have applied ligature on the portal vein in dogs, and other living animals. Müller§ is of opinion that the capillary branches of the hepatic artery and portal veins permit, by their anastomoses, of the secretion of bile from the former vessel. This case, therefore, lends further confirmation to the view which regards the hepatic artery as performing, under certain circumstances, the twofold office of conveying nutritious blood to the liver, and also contributing the pabulum of secretion.

The history of the present case would almost seem to bear out the opinion held by some pathologists, as Armstrong, Breschet, Meli, &c., that intermittent fever is to be referred to phlebitis of the portal system; but although this system suffers in common with other internal organs, there does not appear sufficient evidence to conclude that the *ague* could be regarded as the effect rather than the cause of the latter. In the case before us, the *ague* of which the patient spoke was doubtless merely the occurrence of rigors attending the manifestation of infection of the blood, or the hectic thence resulting. The pathology of intermittent fever points to the derangement of the organs whence originate the roots of the portal veins, as evidenced by enlargement of the spleen; but it certainly affords no proof of its immediate dependence on phlebitis, the effects of which exhibit a far graver character.

* See Edinburgh Monthly Journal, April 1850, for a full abstract of a paper by M. Raikew, read before the Brussels Academy of Medicine.

† Quoted in Edinburgh Journal, p. 363.

‡ Medico-Chirurgical Transactions, vol. v. p. 174.

§ Physiology, translated by Dr. Baly, vol. i. p. 567.

The termination of this unfortunate woman's life was doubtless the immediate effect of the morbid state of the blood, induced by the circulation of pus, superadded to the effects of the previous bad habits of the patient. The effusion of blood within the cranium was a termination, however, common to any form of extensive vascular obstruction; but at the same time it exhibited, at a later period, the usual effects produced on the nervous centres by the presence of pus or morbid matters in the general venous system.

Several other features of this case might furnish the grounds of further remarks; but as the preceding, it is believed, embrace the chief of those that have an immediate reference to the pathology of this case, it may be as well to pass to the notice of the following three interesting cases of jaundice, which have occurred in the writer's private practice, and the origin of which is invested with considerable obscurity.

CASES.—In one family, three girls have each, on arriving successively at about the age of nine years, been the subjects of attacks of jaundice, which have in each instance been attended by the same symptoms. The icteric attack has been ushered in by general malaise and pyrexia; the yellowness of the skin has appeared on the third day, and disappeared in from seven to nine days, leaving slight debility for several weeks. The parents of these children have resided in the same house in an open and healthy situation during these several illnesses; they have since removed to a distance of a few miles, with one female child not yet arrived at the same age; it therefore remains to be seen whether this also shall become the subject of jaundice at the same age; while at the same time the only male child has passed this period without a similar attack. There is no further reason to suppose the existence of an hereditary tendency to this disease than is here stated, as neither of the parents has ever been the subject of the disease.

How can the occurrence of the disease in these cases be explained? Should these be referred to the class of cases which arise out of simple exuberance of the secretion of bile? or, must they be supposed to be owing to some family peculiarity of organization, which the progress of growth causes to inter-

fore with the portal circulation at a particular age? The peculiarity of structure or of nature is the more remarkable, as it must be confined to the females of the family, since their brother, of the age of fourteen, has not exhibited the same phenomena.

Before closing these remarks, it may be worth while to inquire how far disease or obstruction of the portal system may be concerned in certain obscure and intractable forms of hæmorrhage from the bowels, not seldom met with in women who have borne children.

It has occurred to the writer to meet with several cases of obstinate hæmorrhage from the bowels, occurring at uncertain intervals, and varying much in quantity; the blood usually evacuated being of a dark colour, from the chemical action of the secretions of the intestines. In most cases that have occurred to the writer, pain has preceded occasionally, but irregularly, the evacuation of blood, while at other times the purging of blood has taken place with scarcely any warning. In these cases piles or disease of the hæmorrhoidal veins have been excluded, as has also amenorrhœa. The treatment has been difficult and unsatisfactory.

It has appeared to the writer that many of these cases have owed their origin to some disease of the portal system, independent of any interference with the functions of the liver, as jaundice or deficiency of the biliary secretion has not been present. The precise pathological condition to which these are owing is not apparent. In many other cases the source of the hæmorrhage has doubtless been dependent on loss of tone in the vessels of the mucous surface of the intestines.

The quantity of blood thus parted with in the course of a few weeks or months is often very large. The patient assumes an anæmic aspect, as if he suffered from menorrhagia, or puerperal hæmorrhage. In but few cases, however, does this aggravation exist; the menstrual functions are usually normal, and seem to exert little or no influence on the occurrence or amount of the hæmorrhage.

The cases of this kind that the writer has met with have lasted a long time, having existed in one instance as long as fifteen or sixteen years. No oppor-

tunity of making a post-mortem examination has occurred to him. The treatment has been obviously difficult; at times attended with apparent success, then again all efforts have been baffled by a sudden relapse.

CONSIDERATIONS ON THE CLIMATE OF ITALY,

WITH REFERENCE TO THE TREATMENT OF CHRONIC DISEASE.

By JAMES EDWARD POLLOCK, M.D.,

Licentiate of the College of Physicians, and Medical Resident at Rome from 1842 to 1849.

No. III.

BELIEVING that on the comparative integrity of the nutritive function depends the retardation of chronic phthisis in almost all cases, and its cure in the earliest stages, we conceive that too much importance cannot be attached to a careful inquiry made into the state of the chylopoietic apparatus before selecting a marsh climate as a residence, and allaying local irritation in the lungs at the expense of congestion of the digestive organs. We should remember that the natural decarbonising process, and the depuration of accidental impurities from the blood, are shared by the liver, lungs, kidneys, and skin; and that the system is so admirably endowed with a compensating activity, that if one of the elaborators of the surplus material of the economy be deranged, a vicarious and exactly equivalent action is invariably undertaken by some other; that this superfluous waste is more than sufficient to employ for its elaboration the organs remaining healthy, and that their overaction results in engorgements, hypertrophy, and finally in alterations of structure; and that, if in addition to one depurating organ diseased we add the complication of a blood poison of marsh production, which gives rise to supplementary, and therefore difficult processes for its elaboration, we have a formidable state of things to contend against, an increased amount of depuration to be effected, with fewer organs to accomplish it, and a local irritation in one, which should be in a state of increased activity. If it be true that the pulmonary surface offers to morbid atmospheric matters the chief door of ingress to the system, it is natural that

it should also be a chief agent in their elaboration, so extensive an area for the operations of endosmose and exosmose with the blood not presenting itself in any other structure of the body accessible to such agents. Again; the decarbonising function of the lungs is not regarded by us with sufficient attention, yet it is of such vital importance, that it literally admits of no adequate compensation by other organs engaged in a similar task.

The phenomena of asphyxia from mechanical stoppage of the act of respiration should ever be present to us as the type of blood poisoning from retained carbon, and a modification of its symptoms in proportion to the amount of surface thrown out of action may be traced in a regular descent through all affections of the lungs, down to the most minute alterations from a healthy state. Double pneumonia is the nearest approach to a ligature round the trachea in its effects on the blood; general bronchitis comes next; then the one-sided affections. In pleurisy the dyspnoea and distress is more from the pain accompanying the respiratory movements, than from the system feeling a want of aerification; and its diagnosis from a pneumonia may be often facilitated by an observation of the colour of the face, lips, &c., in the latter,—a remark, of course, only applicable to the earlier stages of the pleuritic inflammation,—as in the later the resulting effusion is of itself a cause of non-depuration of the blood by simple diminution, from pressure, of the respiratory surface. Again; in phthisis we must presume that a class of symptoms exists quite distinct from either the local irritation or the constitutional sympathetic fever, but which we do not always distinguish from the latter, and which are referable to non-aerification of the blood, and the resulting retention of a surplus quantity of carbon. To this division belong, to a certain extent, the innutrition of the whole frame, the coldness of the extremities, the loss of rest, and uneasy sensations of the head, the brain being supplied with an impure quality of blood. The great heat of skin observable in many cases indicates the effort made by the cutaneous surface to get rid of the retained carbon; and physiological experiments have left little doubt that an interchange of gases, resembling that taking place in the

pulmonary membrane, does to a certain extent supply the place of the latter, when it is injured or diminished in extent by disease.

These observations may at first sight appear extraneous to the subject of climate, but the possible introduction of a marsh poison into a system whose elaborating powers are already enfeebled, and with one principal organ of depuration diseased, is a consideration of importance; especially as a restoration to health, or even a long endurance of disease, must be the result of an improved quality of the blood, and of strengthened vitality,—a state of things incompatible with the existence in the vital fluid of either a surplus quantity of carbon or of any foreign matter, such as we must suppose the marsh poison to be. To reduce this to practice, the writer can state from observation, that those who are liable to frequent recurring derangements of digestion, especially of the processes of secondary assimilation, or, what is nearly the same thing, to congestion of the liver, kidneys, &c., are not likely to benefit by a residence in Rome or Pisa, nor, as a rule, in any malarious district. The shelter from winds and evenness of temperature which is advisable for the phthical patient of this temperament, is better found in some of our own southern residences possessing these advantages. Derangement of the secondary organs of digestion is so frequent in Southern Italy, that the healthy northern constitution soon feels depressed, and the consumptive are plagued by “bilious attacks,” through which they must either struggle by a difficult and annoying process of elaboration, or have recourse to evacuates, for which they are but little fitted in strength. To this class of patients belong, not only the purely sanguineous who are plethoric, and by high colour, full pulse, and activity of brain and of muscular actions (including the tissues concerned actively in circulation) exhibit the marked features of the temperament, but a far more numerous class, whom we might perhaps designate as possessing the sanguineous diathesis *degenerated*. It is quite possible to have a tendency to overaction of the circulation and a highly excitable nervous system combined with *debility*, a prostration of vital power succeeding its too great exercise, forming, in fact, a feature of

the physiological division of which we are speaking. Debility, in such cases, is apt to be more felt than even by those of constitutionally low tone of fibre, both muscular and nervous. Physiologists are aware of the fact with which the physician in practice is familiar, that acute diseases of severity will often be better borne by those in whom the standard of vital power is uniformly low than by the plethoric or muscular. That such a debilitated state of those endowed naturally with the sanguineous temperament is a frequent—shall we say the most frequent—precursor of the development of tubercle in the English constitution is, we think, borne out by a careful observation of disease. As a nation we are eminently gifted with this temperament, modified by some of its several combinations with the phlegmatic and melancholic; and by it we are tempted to commit excesses in over-exertion of mind and body—mentally, in the race of life ever beginning, never ending, in the competition for wealth and fame by their thousand avenues; and physically, by the bodily craving for the over-stimulating in food and drink to which prolonged activity of mind is so apt to give rise when the cares of the day are over. One nation alone, perhaps, exceeds us in this temperament and its results, and they alone surpass us in the number of consumptive carried off as its victims. Some experience of the American constitution has given the writer unfortunately strong confirmation of this observation. Now the debility which follows the over-exercise of the sanguineous temperament should not be increased by exposure to a *relaxing* climate, and *this class of persons should never be transported to Southern Italy*. These observations on the sanguineous temperament have led to considerations which are easily applicable to various forms of debility; and we would wish to extend our propositions so as to include *all cases of chronic disease with lowered vital powers depending on such alterations of the secondary assimilative functions as are most commonly accompanied by congestion of the liver and kidneys*, and which, of course, are met with in others than individuals of the sanguineous temperament.

For the same reasons as above stated we must confess to the great surprise with which we have seen cases sent to the

South of Italy which were complicated with obscure congestions, manifested by such symptoms as pain in the right side or renal regions, deficient action of the liver, habitual constipation, loaded tongue, yellow conjunctiva, unhealthy stools, cold extremities, weak pulse, and general capillary congestion, with perhaps frequent lithic, oxalic, or other deposits in the urine, and very often by some form of skin eruption; and yet, perhaps many physicians at home would argue that the determination to the surface, which is a known effect of a warmer temperature, and the general stimulus given to the system by the mental as well as bodily occupation afforded by travelling, are sufficient reasons for exporting such cases to a southern air. The second of these ends can be equally attained by travelling in other climates of a more bracing character; but the question whether an increased action of the skin is generally produced by a *winter* residence in any part of the South of Europe is very important, as perhaps no plea is more frequently made use of for sending dyspeptic patients to travel than that of promoting the healthy action of the skin. Nor can we wonder at it, since in the earlier stages of dyspepsia the comfort and energies of the invalid so often depend on the vigour of cutaneous transpiration; and in the more advanced a variety of skin diseases arise, manifestly depending on internal causes, and which, to be relieved by art, must be viewed and treated, not as idiopathic affections, but as symptoms of such derangements.

If the production of diaphoresis, or any less degree of action of the skin, depended on temperature alone, or even principally, there would be a show of reason in thus arguing, although (as we shall afterwards notice) the average *winter* temperature of any part of the South of Europe is absolutely insufficient for this purpose; but as, in fact, the skin capillaries are only part of the great chain of secretive circulation, and the very portion of the circle most dependent on the integrity of the other organs for its uniformity of action, an almost constant want of success attends every effort to promote its secretive powers, unless preceded by an effectual opening of the internal capillaries, be they of the lungs, liver, kidneys, or of the vital mesh spread over the great

mucous canal. The best diaphoretic is, therefore, to cleanse the bowels and restore the internal secretions—a fact daily verified by the observation of the effects of mercury in quickening the action of antimony on the skin, a result which it produces not so much by a specific power over the capillaries, as by freeing the internal obstruction in the secretive circle, and thus permitting the natural action to proceed on the surface, which, if not checked in the liver and kidneys, would (the skin being in a healthy state) have proceeded without interruption. Let us not be misunderstood as undervaluing temperature as an agent in the restoration of the capillary action of the skin; for if the internal congestion be removed, it then becomes of importance as a means of determining to the surface; but we contend that, neither by climate, or by so-called “diaphoretics,” by muscular exercise and frictions, nor even by a high artificial temperature, can we permanently improve the cutaneous functions if internal congestions remain unrelieved. Now the sending a patient with such—be they of the mucous surface, or of the digestive viscera themselves—to a climate where such congestions are produced with facility even on the healthy system, with the hope that the higher and more uniform temperature natural to the place may relieve the skin capillaries which are not in fault, but only evidencing some internal stoppage, is surely as illogical in theory as it is unsuccessful in practice.* That it is unsuccessful in every case presenting the above features, the writer can attest from experience. To sufferers of this kind he has invariably recommended in Rome a *journey to England or Switzerland*, exercise on the mountain side, and avoidance of the plains, abstinence from stimulants, and great moderation in the quantity of food, preceding these measures by an attempt to restore the deranged internal organ by moderate local depletion, and an appropriate me-

dicinal remedy if indicated. That the climate of southern Italy, and of Rome in particular, favour such congestions, is sufficiently proved by their frequent occurrence in the healthy English system exposed to its influence, by the uniform intolerance of even customary stimulants felt by visitors in an ordinary state of health, by the occurrence of headache to an extent which has become proverbial, and of an unusual amount of more serious brain-affections—by the type of the fevers there prevalent, which are either of the pure intermittent form, which we know lead to enlargements of the abdominal viscera as the most common resulting organic lesion; or of a prolonged and intractable gastric character, evidencing congestions of the whole mucous canal. Lastly (and not of least importance), arguing from analogy, by the frequency of urinary deposits, the kidneys being the principal elaborators of poisons received into the system, and such poisons frequently determining the nature of abnormal products in the urine, if they do not absolutely constitute their material.

The above considerations have appeared to us to account for the prevalence of congestive biliary and renal derangements among the English in Rome, and to furnish sufficient reasons to decide us to prefer sending patients in these circumstances to a lighter, purer, and more stimulant air, free from even the chances of marsh influence. Should an irritable state of the bronchial membrane render a mild and sheltered climate advisable, Hastings, Torquay, or Queenstown in Ireland, afford advantageous residences: but should even these prove too relaxing, and that the patient seem depressed rather from want of the nervous power which gives tone to the muscles, vigour to the digestive system, and energy to both mind and body, than from the local irritation in the lung, the philosophic physician will surely not be misled by a name or an exploded theory, but will recommend a removal to an absolutely cold, stimulant, bracing air, such as can only be obtained among mountains, or in a decidedly northern latitude. Careful observation has proved that a calm, dry, cold air, is borne with facility by the respiratory organs. It was only when a wind arose that Ross's men suffered much during their Arctic excursion;

* The great prevalence of certain forms of skin disease in the districts alluded to is another proof of the correctness of this reasoning. Porrigi, in some of its most inveterate forms, is more frequent in Rome than we have seen it in any other city, while an absolutely peculiar affection, not seen elsewhere (pellagra), is localised in the great plains of Lombardy, where the extensive rice-fields, annually flooded and allowed to evaporate under an August sun, are a perfect hot-bed of “malaria.”

and we do not find that the pulmonary apparatus was that most frequently deranged when sickness occurred? A greater vigour of digestion, an increased demand for animal food, and a muscular energy wonderfully sustained, were the healthy results of their exposure. But theirs was an extreme case, and we only use it for illustration. A less degree of cold, and *the absence of currents and moisture*, can be secured elsewhere, if circumstances permit of our sending the invalid to districts where such a climate may be found. We have had, for instance, several opportunities of hearing from the patients themselves experiences on the different effects of the northern and southern parts of the American continent. Indigestion and phthisis, the twin diseases of the United States, are decidedly more prevalent in the central and southern than in the northern districts; and we have received from Canadians and Virginians corresponding accounts of the good influence of the former, and of the pernicious effects of the air in the latter country on individuals debilitated by deranged digestive organs, with a complication of chest affection. We will not enter here on the question how far a cold, dry air, of even temperature, such as Norway affords in the winter, might not be eligible for the consumptive patient, for reasons derived from a consideration of the pulmonary lesion alone, but for the present confine the remark to the good effects of a cold, bracing climate, on the above complication. No better proof of the good effects resulting from a removal from the influence of a sedative, malarious air, could be found than in the advantages which we have often known obtained by removing patients in such circumstances from Rome to the Alban Hill, or to some of the villages on the Sabine and Volscian chain of mountains, where in old days Horace and Cicero, and perhaps all patrician Rome, were wont to retire for pure air from the stagnation of the busy capital.

[To be continued.]

APPOINTMENT.

MR. HIGHLEY, of Fleet Street, has been appointed by the Royal College of Surgeons Bookseller to that Institution.

AN ESSAY ON UNHEALTHY INFLAMMATIONS.

BY M. BROKE GALLWEY, ESQ.

Assistant-Surgeon Royal Regiment of Artillery,
Woolwich, Kent.

[Continued from p. 1014.]

ERYSIPELAS (continued).

SOME of the most original and philosophic remarks that have graced the medical literature of our own country on this disease, will be found in the No. of the *Lancet* for March 1844, from the pen of Dr. Arthur Wilson, of St. George's Hospital. I may say, I believe, that I have pretty nearly waded through everything that has been written, in ancient and modern literature, upon erysipelas; and I know of no author who, in a very small compass, has delivered himself of so much valuable matter upon the *natural history* of the disorder. "Erysipelas," says Dr. W., "may be described as a *severe depressing fever*, lasting from eight to twelve days, and determined, by a special effect of inflammation, to that peculiar organic structure, the integuments of the head and face. Like other fevers, it often supervenes on any of the various causes that induce a bad state of the general health" (p. 11-12). "Like the other eruptive fevers of this country, erysipelas, in bad cases, always becomes typhoid towards its close. Its pathology, by dissection, is that of scarlet fever, which, in its several stages, it very much resembles" (p. 12). Again: "Regarding its symptoms, whether local or general, as a train of actions *tending of necessity to their own relief*, we should, in most cases, be content to watch over their safe development, and to wait patiently for the result, which, in this fever, soon arrives. Idiopathic erysipelas, within ten days from its invasion, seldom fails to cure itself" (p. 12). The following is a severe but just satire upon the thousand and one contrivances devised by physicians to thwart and defeat Nature's efforts when oppressed by this poison:—"In our application, by treatment, of these principles to the local effects of the disease, while we are careful to protect from lasting injury the structures in which its action is most declared, we should continually remember that *in the progress of the eruption is the ad-*

vancement of the cure. It is under an imposed task of swelling, vesication, and excretion, that the skin, which bears the strain of this fever, is enabled to relieve the other vital organs, and, in the end, to maintain its own integrity. How rash and mischievous the interference that would seek to mislead the actions thus determined to the surface, by the introduction of belladonna to the system already charged with morbid poison in the blood,—that would prescribe, in all cases of the disease, an exact limit to its eruptive action, by pencilling the inflamed face and scalp with designs in lunar caustic! The mask which, in erysipelas, the patient is compelled to wear, should never be adapted by his physician!" Again, speaking of the *natural course* of some diseases, and of the fact that their *ebullitions* have a tendency to work out a "good and wholesome result," Dr. Wilson well observes—"The practical application of this principle in the treatment of disease is a continual rebuke to the vanity that would in all cases attribute the interruption or alteration of symptoms to the efficacy of the last prescription. There is no better test of the physician's general character than is afforded by his practice in erysipelas. From the rapidity with which its symptoms are developed (generally to a good end), much of the treatment in this fever is superfluous, yet much affects to be specific: and thus the boaster triumphs in a cure where the true physician is content with acknowledging a result" (p. 13).

There is much more in the paper from which I have been quoting that merits our serious attention. But I have done an injustice to its merits in that part of my essay where they should more appropriately have been noticed—to wit, under the head of what I had to offer upon the morbid condition of the blood in erysipelas; for, the primary object with Dr. Wilson has been to establish the *constitutional* nature of this disease, having its departure, its rallying point, and, indeed, its entire essence, in a blood-poison. I have reason to know that, for years before the publication of his remarks on erysipelas, Dr. Wilson had laboured at St. George's to establish the great truths of the humoral pathology; but that those labours were sneered at by some, and openly ridiculed by others incapable of appre-

ciating their importance. And, it cannot but be gratifying to this estimable* physician to witness the *almost rush* with which the tide of opinion is now setting in this direction. Copernicus was beaten with many stripes for asserting that the earth moved round the sun; and, on rising from beneath the uplifted arm of the oppressor, he still muttered out, "*And it still moves round the sun, for all this.*" Dr. Wilson was nothing daunted by those who inflicted stripes upon his adopted; and his consistent support of it ever since bespeaks the fondness with which, all along, it had lain in his bosom. Verily, he has his reward.

Dr. Graves has an interesting chapter, in the second edition of his work on Clinical Medicine, upon erysipelas, with the merits of which I must detain the reader for a moment. "Erysipelas, you are aware," he says, "is generally looked upon as an inflammatory disease, and its treatment is always more or less antiphlogistic (?) during the early stage. At this period, it is customary to treat it with general bleeding, leeching, scarifications, purgatives, mercury, and tartar emetic; and, I will allow that many cases should be treated in this manner. But, the gentlemen who have attended this hospital

* I trust Dr. Wilson will forgive me for dragging him before the public in this place in a character additional to that of a *writer* who has deserved well at our hands. Having occasion to be at St. George's on two occasions not long after the commencement of the present medical session, I had the pleasure of profiting by a clinical address which this physician happened to be delivering to his class at those moments. And I cannot resist alluding to the feeling and eloquent terms in which, on each occasion, he pleaded with his auditors for tenderness, for sympathy, and for kindness in their dealings with the poor souls who were so much at their mercy within those walls. I wish in these remarks to make no invidious comparison of Dr. Wilson with other public teachers of the day: far from it. I believe kindness to the poor inmates of our public hospitals to be the rule, and the opposite the rare exception. Only, I could fondly wish that our hospital physicians, in their solicitude to interest the pupil in the disease, were more systematically to plead with him for the *patient*, so prone are we, especially by indulging in the habit *early*, to sink the interests of humanity in those of an absorbing science. Having seen Dr. Wilson on these occasions for the first time in my life, I shall not, I am sure, be misinterpreted in the passing tribute here paid to his heart as well as to his head. But, I honour the man who, amid the bustle and anxieties of public life, can halt by the road-side to drop a tear himself, and to ask one from his neighbour, for the sons and daughters of misfortune. And let none of us forget that "he that hath pity upon the poor lendeth unto the *Lord*; and that which he hath given will he pay him again."

within the last three months have witnessed a form of erysipelas which required, from the beginning, an exactly opposite line of treatment. In the management of the cases which fell under our observation, no one in his senses would think of using general or local depletion, purgatives, or tartar emetic. The moment the disease appeared we were obliged to attack it with tonics, narcotics, and stimulants" (p. 321-2). Dr. Graves continues—"I have seen many instances in which this affection appeared in a distinct and well-marked inflammatory form; and I have treated cases with venesection, leeching, purgatives, and tartar emetic, and found these means admirably well fitted to remove the disease" (p. 322). Dr. Graves then introduces two cases, which I humbly here submit as good illustrations of what I would call the *artificial form* of the disease, *which, if not manufactured, is greatly aggravated, by the nimis diligentia* of the physician. "Mrs. B., a lady of middle age, was attacked with feverish symptoms. Notwithstanding the *diligent employment*" (query, *more Mr. Lawrence?*) "of antiphlogistic treatment by Mr. Barker, the pyrexia increased. In the course of a few days her throat became sore, and shortly afterwards erysipelas appeared on the face. Her case assumed a very dangerous aspect. She continued seriously ill for some days, and was saved with some difficulty" (p. 323).*

The son of this lady, a youth of 18, contracted erysipelas whilst closely engaged in attendance upon his mother. While employed in fomenting her, "he got, to use his own expression, 'a whiff of sickening air from the bed-clothes,' and immediately felt unwell."

This second case appears to have been first treated by Mr. Carmichael, who *twice leeches* the patient for headache, and ordered a continuance of "antiphlogistic and aperient medicines." He was "leeches freely twice," at a later period, on the trunk, for some fullness and tenderness, in which locality erysipelas afterwards developed itself. During

the whole of this period he manifested an extraordinary restlessness and nervous excitement, having, in one night, "changed from one bed to another at least one hundred times"—a condition alone, I should say, contraindicating the removal of blood. Well, in less than a week after the last application of leeches (Dr. Graves had been called in in the interim), "nearly the whole of the right side of the abdomen and the scrotum was superficially gangrenous;" and the wind-up of the case may be surmised. To meet that argument which might be raised, in explanation of the gangrenous sequelae, by the *inflammatory* philosophers, I shall add, in the words of the author—"It is worthy of notice that the gangrene did not originate in the excessive violence of the cutaneous inflammation; for, it did not appear in those portions of the skin which were primarily and most violently affected. On the contrary, we observed that the parts which became gangrenous had been paler and less tense than those which did not assume that condition; and that the portions of the skin which died were those which had become engaged in the latter stage of the disease" (p. 325).*

Dr. Graves presently adds—"I am anxious to impress upon the minds of my younger auditors that there are certain forms of disease, termed inflammatory, in which the ordinary treatment by depletion is quite inadmissible" (p. 326).

I know not what Mr. Lawrence, *et hoc genus omne*, will have thought of this *unhandsome* declaration! I strongly recommend a perusal of the rest of this chapter to such practitioners as may still be under the dominion of their early blood-thirsty conceptions in connection with this disease. Dr. Graves does not appear to be acquainted with Dr. Robert Williams's admirable article on "The Poison of Erysipelas,"† if I

* Sauvages, Cl. III. Ord. i. 2, relates the case of a lady who was bled *fourteen times* for a typhoid or gangrenous erysipelas, and yet was not killed by her doctors!

Andral records a case in which erysipelas ensued in the punctured parts in an anasarctous subject, the erysipelas speedily passing into gangrene. In connection with this subject, he says—"La mort fut évidemment le résultat de l'érysipèle gangréneux qui s'empara de la peau de l'une des jambes à la suite des scarifications." "Certes," he adds, "la terminaison de cet érysipèle par gangrène ne sera point ici attribuée à un excès d'inflammation."—Clinique Médicale, Maladies de l'Abdomen, vol. iv. p. 206.

† Elements of Medicine, vol. i.—The Morbid Poisons. By Dr. Robert Williams.

* I have elsewhere endeavoured to show (vide *Lancet*, Nov. 24th, 1849) that Dr. Graves occasionally wields these powerful weapons in very inappropriate cases; whence I look with suspicion upon the *prudence* with which they may have been employed in his hands in erysipelas—a distrust sufficiently excusable, it is hoped, in the writer, who believes them at all times unnecessary, if not injurious.

may judge from the silence which that physician's precept—to treat the disease systematically with wine—has experienced in a didactic address.

"Another way," says Dr. Watson, "in which erysipelas may kill, is by gradual *asthenia*. Without any stupor or much wandering, without any marked affection of the breath, the pulse becomes weaker and weaker, the surface cold, and the heart at length ceases to pulsate"*

"Erysipelas further resembles the disorders of the group in which I have placed it, that it sometimes prevails *epidemically*; and, on those occasions, like the rest of the group, its occurrence is promoted by all the circumstances that tend to debilitate the body,—by intemperance, by previous disease, by low spirits and anxiety, by insufficient nourishment, and by foul air" (p. 831).

In relation to the question of treatment, after stating his opinion that the *in medio* will be found the safest rule in practice, and, in particular, that erysipelas "is not to be *cut short* by any particular mode of treatment,—that it will run a certain course, and that it will *generally* terminate, sooner or later, by resolution, whether remedies be employed or not,"—Dr. Watson adds this observation—"If you look at the history of erysipelas, and of the notions which have *prevailed* respecting it, you will find that the opinions in favour of giving support, and of abstaining as much as possible from the abstraction of blood, greatly preponderate." Again: "In most instances you will soon perceive evidence of great debility,—a *feeble* as well as a *frequent* pulse, tremors, a dry and brown tongue often; and these symptoms increase if you *then* persist in drawing blood. The carbonate of ammonia does great good sometimes in such a condition; and this I am very much in the habit of giving. The bad cases of erysipelas are apt to baffle us all. I am not aware that I lose more of them than my neighbours. Speaking generally, a large majority of my patients get well; but, I do not bleed one patient in a hundred from the arm."

Dr. Watson subsequently states, that "in the purer air of the country, and in young, strong, vigorous country persons, bleeding may be proper and,

requisite" (p. 832-3). Altogether, I am bound to declare that in my opinion very little information is to be gained from Dr. Watson in relation to the management of erysipelas, and that, in the counsel he affords to his readers, there is far too much of the *blowing hot and blowing cold* with the same breath.

"It is always to be remembered," says Chelius, "that erysipelas, even when connected with inflammatory fever, will not bear the same active antiphlogistic treatment as other inflammations, and is especially prone to *return* after any exhaustion."* And Mr. South, in allusion to the above, is still stronger in his condemnation of depletion:—"Bleeding, either from the arm, or by leeches, from the head, is, I believe, very unadvisable. The disease almost invariably occurs in constitutions without power, and therefore bleeding *favours rather than diminishes it*." This is pretty strong, I think, in condemnation of depletion—"Bleeding favours the disease!"

In the course of his Lumleian Lectures, the adynamic nature of erysipelas, and its immediate dependence upon a blood-poison, have been insisted upon by Dr. Todd in the most unqualified terms. Indeed, so forcibly does this eminent writer consider it a disease of low power, that he characterises "*alcohol as an antidote to the erysipelatous poison*," and treats the disorder in all cases and under all circumstances, if I mistake not (for I quote now from memory), with brandy.

Dr. Copland describes erysipelas as "an *asthenic* inflammation depending upon constitutional disorder."† Like Mason Good, he speaks of an "erysipelatous diathesis," which appears to him "to be connected with great irritability or tenderness of the cutaneous surface, and *defective power of the capillary vessels* and secreting surfaces and viscera" (p. 823). Among its most frequent predisposing causes he ranks "feeble, leucophlegmatic, and plethoric habits, unwholesome and low diet, general cachexia, and exhaustion of vital or constitutional power," &c.; and in that portion of his elaborate article on erysipelas which is devoted to the "nature" of the disorder, he observes—"The diffusive character of the

* Principles and Practice of Physic. 2d ed. vol. ii. p. 829.

* Vol. i. p. 106.
† Dictionary of Practical Medicine, vol. i. p. 818.

inflammation, whatever tissue it may attack, is referrible entirely to defective vital power, to the changes in the circulating fluids, and to the imperfect tone of the extreme vessels: these conditions being inadequate to the formation of coagulable lymph: the products of inflammatory action in this state of vital power, and of vascular action and impurity, being a turbid, puriform, ichorous, or sanguineous serum, which produces a septic effect, or poisons the adjoining parts, especially the cellular tissue" (p. 827). Considering that Dr. Copland insists very strongly upon the intrinsically *asthenic* nature of erysipelas, there is, to my mind, some inconsistency in the terms with which we behold him flirting with the lancet in his management of the disease. "In some instances," says he, "large depletions are required; in others, moderate or local depletion only is admissible; and in many, depletion is most injurious, the most energetic tonics being often indispensably necessary" (p. 828). And, in speaking of the "phlegmonoid" form of the disease, he adds—"Depletion and other evacuants should be prescribed with a promptitude and to an extent co-ordinate with each, and with a due regard to the circumstances of the case: always recollecting that, in diseases like this, which are connected more or less with imperfect excretion and a morbid state of the circulating fluids, vascular action may be excessive, whilst nervous power and vital resistance are reduced to the lowest states; and, therefore, that vascular depletion, in order to be salutary, or even not to be injurious, should be rarely employed, and with strict attention to its effects, both at the time and immediately afterwards" (p. 831).

While much of the same diversity of opinion exists in France, as to the true nature of erysipelas, which characterises the professional mind in this country, the balance inclines decidedly, as with ourselves, in favour of its *asthenic* associations. I have already quoted the decided views of Dupuytren as to the necessity which he considered the disease to lie under for copious evacuation. M. Boyer would appear equally favourable to free depletions in the phlegmonous form of the disease—"On proportionne le nombre des saignées à la violence de la maladie, à l'âge du malade, à son tempérament, et à l'état

de ses forces avant le développement de l'érysipèle."* In the other varieties of the disease (of which he enumerates several), M. Boyer counsels his readers to use much circumspection in the employment of depletion. He was much under the dominion of Desault's views as to the immediate dependence of erysipelas, when not arising from a "cause externe," upon a vitiated state of the bile ("elle consiste dans un amas de bile de mauvaise qualité"—p. 10); and considered internal remedies addressed to the liver and first passages as of primary import for its relief.

Lepelletier says that in France the greater number of practitioners are agreed on the danger of bleeding in the majority of cases of erysipelas, and that this operation ought not to be had recourse to but when the inflammation *marche franchement*, the patient *plethoric*, the fever violent, and the pulse full. Blache and Chomel say experience has proved that general bleeding has often no other effect than to blanch the eruption (*pâleur l'éruption*) without notably abridging its duration. Bauquier, in his account of the practice of the hospitals de la Pitié et de Cochin, says that M. Bally abstained altogether from bleeding, or the application of leeches, in his treatment of erysipelas of the face; for he speaks of it "comme propres à aggraver les symptômes, à faciliter l'invasion du délire, à lui donner de l'intensité, et à prolonger la maladie." Bauquier also states that the only cases of erysipelas, according to his observation, attended with danger, were those in which antiphlogistic treatment had been employed.†

Andral gives us the history of a man, who, in good health, began suddenly to manifest a dropsical disposition, which was treated by punctures. The day after this operation "la cuisse droite était devenue le siège d'un vaste érysipèle qui en occupait toute la partie supérieure interne. La douleur qu'éprouvait le malade dans cette partie était assez vive pour lui arracher des cris." On the next day "l'érysipèle s'était étendu; toute la cuisse était dure et douloureuse; les bourses s'étaient prodigieusement tuméfiées depuis la veille; le pouls était très fréquent, la peau chaude."

* *Traité des Maladies Chirurgicales*. Par M. le Baron Boyer. Vol. ii. p. 17.

† *Elements of Medicine*. By Dr. Robert Williams. Vol. i. p. 279-80.

A large slough soon followed. The erysipelas extended to the anterior walls of the abdomen, and the patient died invoking death, his head quite clear, and "le poulx très petit, d'une extrême fréquence." The internal organs manifested so remarkable a deficiency of blood, that M. Andral observes—"On dut dit du cadavre d'un individu mort d'hémorrhagie."

His concluding remark upon this anæmic condition is interesting, and, to our present purpose:—"Enfin, au milieu de cet état anémique, une congestion de sang s'opéra, néanmoins, là où des piqûres, pratiquées pour faire écouler la sérosité, avaient appelé une légère irritation,—preuve, entre mille autres, que la production de l'inflammation ne dépend pas d'un état pléthorique; et que, dans plus d'un cas, comme on la déjà dit, quand même il ne resterait qu'une seule goutte de sang dans l'économie, elle fluait vers le point irrité. C'est là, pour le dire en passant, une des grandes objections que l'on peut faire à la méthode généralement adoptée en France, qui consiste à ne combattre tout travail inflammatoire que par des émissions sanguines plus ou moins abondantes. Il est bien certain, cependant, que si par ce moyen on opère un *déorgement momentané dans la partie inflammée, on ne détruit en aucune manière la cause inconnue sous l'influence de laquelle le sang, soustrait aux lois ordinaires de la circulation, tend à s'accumuler sans cesse le point où existe le travail d'inflammation.*"

[To be continued.]

M. ROYER-COLLARD.

LATELY at Paris, in his 47th year, Dr. Hippolyte Royer Collard, Professor of Hygiene in the Faculty of Paris. The name of the deceased has been long known to men of science in Europe. The French journals are filled with maudlin sentimental orations delivered over the grave of the deceased, but they give no biographical account of the deceased, or his labours. He was born to comparative wealth, and the great stimulus to exertion—necessity, which has carried forward others to the highest rank in the profession, did not exist in his case. M. Royer-Collard has filled the professorship of Hygiene in the Faculty, and has died in the prime of life, regretted by his colleagues and pupils.

* Clinique Médicale—Maladies du Poirtrine, vol. i. p. 123, et seq. The *italics* in the foregoing passage are my own.

MEDICAL GAZETTE.

FRIDAY, DECEMBER 27, 1850.

IN the present number we bring to a close the forty-sixth volume of this Journal. The large portion of our space which is necessarily occupied by the Index, prevents us from doing more than taking a brief retrospective view of its contents. In the LECTURE department of the Journal we have presented to our readers the valuable lectures of PROFESSOR PAGET on Inflammation, and the sequel to the Lumleian lectures of DR. TODD. A course of CLINICAL LECTURES on Practical Medicine has also been contributed by Dr. Todd. We have reason to believe that these lectures have been well received by the profession, as practical and original contributions to medical science. They display careful observation, sound induction, and a thorough knowledge of physiology and pathology. It is with satisfaction we announce that this valuable course will be continued in the new volume. In this department of our publication, we must not omit to enumerate a short but instructive course of lectures on the Medical Jurisprudence of Insanity, by DR. ROBERT JAMIESON, of Aberdeen, and the lectures on Diseases of the Heart, by DR. O'B. BELLINGHAM, of Dublin. The reputation which this gentleman has already acquired by his researches on Diseases of the Heart, and his practical improvements in the treatment of Aneurism, is fully sustained by the course of lectures, of which the first part has just been brought to a close in the present volume. The second part of the course will be devoted to the consideration of special diseases of the Heart. The publication of this part will be for the present postponed.

A large portion of the volume is occupied by ORIGINAL PAPERS contributed by gentlemen whose names are well known to the profession, and they embrace subjects relating to every department of Practical Medicine. They indicate the progress of Medical Science in all its branches, and convey to the practitioner that kind of information which can be supplied only by periodical medical literature.

In the REVIEW department more than one hundred works have been noticed in this volume; and these notices have been uniformly inserted without favour or partiality to authors or publishers. The number of works almost weekly remitted to us for review, is a proof that authors and publishers have confidence in the spirit of justice which prevails in the reviewing department of this journal.

Of the PROCEEDINGS OF MEDICAL SOCIETIES in England and France, we shall only remark, that they constitute a very important part of the contents of a weekly periodical, whereby it must be greatly distinguished from any monthly or quarterly publication. In addition to the papers read at the London Societies, the reader will find a regular weekly summary of the proceedings of the Academies of Medicine and Sciences of Paris, a feature which is peculiar to this journal. The Proceedings of those useful Provincial Societies,—namely, the Liverpool and Newcastle Pathological, are exclusively published in the MEDICAL GAZETTE.

The publication of HOSPITAL REPORTS in the form of cases observed in our great metropolitan hospitals, as well as in the Hospitals of Paris, will be continued in the new volume. We have made arrangements for the weekly insertion of these reports, which will be drawn up by competent observers.

The CORRESPONDENCE and MEDICAL INTELLIGENCE furnish information on

all the current medical topics of the day: and we believe we may confidently state that no event of any interest to medical men has occurred during the last six months which has not been duly recorded in our pages. We shall only remark, in conclusion, that the principles which have hitherto guided us will be carried out in the new volume. The professedly "high moral" tone may present some attractions to sentimental readers who trust to flourishing promises in advertisements; but a medical journal must be judged not by what its editor or publisher promises, but by that which it really contributes to the instruction of medical practitioners and the advancement of medical science.

We have to announce for publication, in the early numbers of the new volume, the following papers, which are now in hand:—"A Series of Cases of Arsenical Poisoning," with remarks by Dr. OOSTON, of Aberdeen; "Notes on the Structure of the Teeth," with engravings, by Mr. C. S. BATE, of Swansea; "On the Morbid Dynamics of the Nervous System," by Dr. THOMAS WILLIAMS, of Swansea; "A case of Lateral Curvature and Excursion of the Spine, with severe Spinal Irritation," by SAMUEL HARE, Esq.; "Observations on the Practice of Physic," by Dr. CHILD, Consulting Physician to the Westminster Dispensary; "On the Duration of Human Pregnancy," by Dr. T. G. MELHUISE; "On the Effects of Concussion of the Spine," by JOHN GRANTHAM, F.R.C.S.E.; "On the Treatment of Hydrocele," by Mr. R. OKE CLARKE; "A Case of Diabetes," by Dr. F. J. BROWN; with a continuation of the papers of Dr. POLLOCK, on the Climate of Italy; of Dr. TILT, on Ovarian Tumors; and of Mr. GALLWEY, on Unhealthy Inflammations.

Medicines.

The Bath Waters: their Uses and Effects in the Cure and Relief of Chronic Diseases. By JAMES TUNSTALL, M.D., &c. 12mo. pp. 144. London: Churchill. 1850.

THE author has observed, as Resident Medical Officer of the Bath Hospital, that the thermal waters of that place are at present almost exclusively used by the poor, and that while the Hospital is full, the Baths and Pump-Rooms are comparatively deserted. The reason that the middle and upper classes do not avail themselves of these baths is, according to Dr. Tunstall, because no work specially devoted to Bath waters has issued from the press for a period of nearly thirty years. Dr. Tunstall, we suppose, is anxious to remedy this defect; and with that view has written this interesting little work, in which the history, properties, and composition of the waters, are all most fully treated of. The diseased conditions in which the use of these waters are admissible, as well as the reverse, and the diet and regimen to be observed under their employment, are all discussed at sufficient length.

An ingenious and novel form of diagram forms a frontispiece to the volume, and shows at a glance the diseases in which the Bath waters are useful, as well as their comparative utility in different diseases.

The study of this work may much assist the practitioner in his recommendation as to change of residence, &c., and may save patients long and expensive continental tours.

A Practical Treatise on the Therapeutic Uses of Terebinthinate Medicines; with Observations on Tubercular Consumption, Gout, Mineral Waters, &c. By THOMAS SMITH, M.D., &c., &c. 8vo. pp. 95. London: Longman. 1850.

THIS volume comprises a history of terebinthinate drugs, with mention of the authors by whom they have been chiefly recommended; their physical and chemical properties, and modes of

preparation; their physiological and therapeutical effects. This portion of the work occupies eighteen pages. Following thereon are forty-seven pages occupied with illustrative cases; the remaining thirty-seven pages are devoted to several Appendices on the subjects indicated on the title-page.

Although we grant that the author has not erroneously named the work a *practical* treatise, we think nevertheless that its size is greatly disproportionate to its contents, which might have been contained in, and been far more useful as, a short pamphlet. The value of terebinthinate remedies has been long admitted by the profession; therefore their efficacy in certain diseases did not require to be established by the large number of cases reported in this work.

A Practical Synopsis of Diseases of the Chest and Air-Passages, with a Review of the several Climates recommended in these Affections. By JAMES BRIGHT, M.D., &c. 12mo. pp. 271. London: Churchill; Hatchard. 1850.

DR. JAMES BRIGHT here submits the results of his experience in the study of diseases of the chest, and of the best means for their alleviation. "In order to enhance the utility of this synopsis," he also favours his readers with twenty-five pages on the A B C of the anatomy and physiology of the organs of respiration, in order to complete which he has availed himself "of the excellent treatises of Dr. Bock, of Leipsic, and of MM. Barth and Roger of Paris, as both are replete with valuable information." Has the author felt obliged to travel so far for elementary works on these subjects, because he could find none in England "replete with information?"

We are not able to point out in this book any features possessing the attraction of novelty, or the importance of originality.

Notice of an Unpublished Manuscript of Harvey. By G. E. PAGET, M.D. Pamphlet. 8vo. pp. 20. London: Longman and Co. 1850.

THE Manuscript here alluded to consists of rough and concise notes, forming a syllabus of a course of Lectures on

the Muscles of the human body. It was found in the Sloane collection of MSS. at the British Museum. Owing to the extreme rarity of Harvey's handwriting, some doubt existed as to the genuineness of this MS., but the writing has been identified to be Harvey's; other circumstances also have been mentioned by Dr. Paget which confirm the authorship. The general observations made by Dr. Paget on the remains of Harvey's writings are highly interesting.

Proceedings of Societies.

MEDICAL SOCIETY OF LONDON.

December 31, 1850.

MR. HIRD in the Chair.

Erysipelas in an Infant.

MR. H. SMITH detailed the particulars of a case of erysipelas in a very young child. The disease was erratic in its course. It commenced in one of the knees, subsequently it attacked the scrotum, producing a slough; after having apparently subsided, it returned in the other knee; the patient eventually recovered. Mr. Smith considered it was an interesting case, on account of the extreme youth of the patient, and the circumstance of recovery from so severe a disease taking place in an infant.

Anencephalous Fetus.

MR. BORLASE CHILDS exhibited a fetus of the above description. The upper portions of the frontal and occipital bones were undeveloped, as well as the squamous portions of the temporal bones. The cranial cavity was occupied by a pulpy vascular mass. Mr. Childs gave the opinions of many authors who had treated of this deformity, and stated that he looked upon the specimen produced by himself to belong to the second of the two varieties described by Geoffroy St. Hilaire.

A communication from Mr. Edwin Lee was read by one of the secretaries upon Functional Paralysis.

[Neither the paper nor the discussion which followed was of a nature which would render a report of it interesting to the reader.—*REP. MED. GAZ.*]

LIVERPOOL MEDICAL AND PATHOLOGICAL SOCIETY.

November 1850.

Calcareous Concretions from the Lungs.

DR. TURNBULL showed some calcareous concretions, varying in size from a pea to a small bean, taken from the lungs of a patient who had died in an advanced stage of phthisis. The right lung contained several of these deposits, and there were also several cavities, apparently of old date, filled by false membrane, almost resembling mucous membrane. The larynx was ulcerated, and the liver was fatty.

DR. TURNBULL thought that the deposition of calcareous matter generally indicated a tendency to recovery, and that in this case there had been recovery from some old previous formation of pulmonary abscesses, which had left calcareous matter behind, and that the patient had been carried off by a more recent attack.

DR. NOTTINGHAM doubted the connection between phthisis and calcareous deposits, as he had found them without any tubercular affection.

MR. BANNER questioned whether they were any thing but deposits in the bronchial glands, which are not uncommon.

DR. TURNBULL was still of opinion that they were connected with pulmonary consumption, because he had found them principally in the upper lobe of the lungs, and in every stage, from soft tubercle, to hard calcareous matter.

MR. BALMAN confirmed this opinion, by stating that he had found sufficient animal matter, even in the hardest of these concretions, when the earthy matter had been removed by muriatic acid, to prove distinctly under the microscope that it was lung tissue.

Death from Caries of a Rib. By

DR. TURNBULL.

The patient died rapidly from an acute attack of pleurisy, following obscure pain in the back, with slight difficulty in making water, and very indistinct fluctuation in the region of the kidneys.

Post-mortem.—The last rib was found to be carious, which had caused the acute pleurisy of which he died; and also a large abscess in the psoas muscle, the occasion of the slight fluctuation.

Air or Water Pessary.

MR. HIGGINSON showed an ingenious contrivance for acting as a pessary, as a plug to check extensive hæmorrhage, or for dilating the os uteri. It consisted of a

common small bladder, into the neck of which a gutta percha tube is inserted and secured. Whilst flaccid the bladder was to be introduced into the vagina, or even so far, if needful, as through a partially dilated os uteri; and an enema pump, or elastic bottle, being fitted to the gutta percha tube, air or water might be injected into the bladder, until it was distended so as to fill the vagina, or to dilate the os uteri to the required degree.

Hydatid Degeneration of the Chorion.

By MR. HAKES.

The patient in this case was supposed from circumstances to be only two months pregnant, though the abdomen was as large as that of a patient after delivery of the child; but before the expulsion of the placenta symptoms of miscarriage came on, which terminated in the expulsion of about three pints of hydatids. No fœtus could be detected in the discharged mass, though it was carefully sought for.

Abscess of Spleen. By MR. HAKES.

Miss W—, æt. 20, more than ten years ago suffered from rheumatism. Two months before death varicella occurred, accompanied with acute fever: on convalescence she went into the country, and took all sorts of exercise without any feeling of ill health, or affection of the respiratory organs. A month before her death she was attacked by a disease resembling ague, rigors followed by sweating, coming on at first twice in the twenty-four hours,—morning and evening,—leaving her well in the intervals; afterwards but once a day, and later still only once every other day. During the paroxysm she was harassed by violent palpitation, and her pulse ranged from 110 upwards; in the interval the pulse sunk to 60 or 90. Towards the close vomiting distressed her.

The cardiac sounds were listened to for the first four days attentively, and afterwards from time to time, but no abnormal sound was heard till about six days before the end, when a murmur with first sound was present, and from that time till death. A few days before death a very slight amount of œdema of the feet and ankles was visible.

Two or three days before death she was seized with acute pain in the foot, followed after a few hours by blackness of the great toe; next in the other foot, with blackness of the little and neighbouring toes; and afterwards a black spot appeared in the palm of the left hand.

No abdominal tenderness could be detected, though sought for with care.

Autopsy, July 27, 7 P.M.—Lungs crepitating, posterior lobes friable, loaded with much frothy mucus; left lung entirely adherent to walls of chest by old adhesions.

Pericardium contained two or three ounces of dark-coloured serum, rather turbid, with flaky or cloudy lymph. No congestion of its vessels. Heart's size natural. Its cavities contained coagula, extending into the veins. Right side healthy.

Great degeneration of valves of the left side. Of the three aortic valves, two were healthy; of the third, nothing appeared natural but its free edge. The lamina of the valve was gone, and had given place to a number of warty-looking soft vegetations, growing from the attached margin of the valve, but allowing free passage of the blood between them, from the aorta into the ventricle. Both surfaces of that lamina of the mitral valve next to the diseased one of the aorta were profusely covered with the same growths, and at one or more points the growths from the two valves were continuous. No increased vascularity, nor staining of any of the valves.

The vegetations were pale straw colour, or very nearly white, very soft, and appeared to consist of concentric laminae.

Spleen of normal size. On its surface, and elevated a little from it, were two straw-coloured projections, elastic, one triangular in shape, the other forming a band across the viscus, three-fourths of an inch in breadth. These were seen in a section to penetrate about an inch into the structure of the spleen, and consist of straw-coloured purulent matter, of the consistency of thick cream.

Liver and kidneys healthy.

Mr. LONG mentioned Rokitsanski's observation of the frequent occurrence of abscess of the spleen along with disease of the valves of the heart, and thought the connection between them might be explained as follows:—The spleen is a reservoir for venous blood before and after digestion, and easily becomes distended with blood. During the cold stage, described in this case, the blood would accumulate in all the viscera, which would be thereby predisposed to disease. The patient then had an attack of endocarditis, according to the history of the case, which caused violent palpitations; thereby affecting the spleen still more, and terminating in abscess of that organ, and degeneration of the valves of the heart.

Dr. HILBERS confirmed the remark about the connection between valvular disease and abscess of the spleen. He had seen cases of it in Vienna.

Dr. INMAN remarked upon the active exercise that the patient had taken shortly before her severe illness, and alluded to the suddenness with which acute symptoms of heart disease sometimes show themselves

after long concealment. A man felt a sudden violent pain in the heart, having been perfectly well up to that time, as far as he knew. He died, and the mitral valve was found to be ruptured.

Dr. NEVINS mentioned another case in confirmation of this:—A navigator fell into a dock whilst excavating it, and was killed on the spot. On examination of his heart, calcareous deposits, the length of the first joint of the little finger, were attached to the border of the mitral valve; yet he had continued at his laborious occupation up to the moment of his death.

ACADEMY OF MEDICINE, PARIS.

Dec. 10, 1850.

Electro-physiological Researches on the Functions and Endowments of the Chorda Tympani.

Dr. DUCHENNE transmitted an analysis of a work on this subject. The author stated that having limited the galvanic excitement to the chorda tympani in a healthy state, there had been produced a sensation of tingling, pricking, or itching in the anterior two thirds of the tongue on the side galvanized. A higher degree of galvanic stimulation had produced a metallic taste on the tongue. During the operation no muscular contraction of the tongue or velum palati, nor any modification of the state of the papilla, or augmentation of the mucous or salivary secretion, took place. These phenomena were not observed where paralysis of the seventh pair existed. From these facts Dr. Duchenne concludes that this nerve is appropriated to the gustatory function of the anterior two thirds of the tongue.

The Treatment of Gout and Rheumatism.

M. LEVRET, of Lyon, addressed to the Academy some conclusions at which he had arrived on the nature and treatment of gout and rheumatism, both of which he considered as being specific diseases, consisting of an inflammatory and a poisonous element; that their causes act directly on the stomach and indirectly on the skin and nervous centres, while the disturbance of these organs reacts sympathetically on the assimilative functions; that its treatment consists in the use of medicines which exert a special action on the elements of the disease; and, that the preparations of colchicum are those specific remedies.

Annual Reports on Epidemics—1849.

M. GAULTIER DE CLAUDEY read the report of the Commission, from which it appeared that seventy-two reports had been received from physicians in the departments.

These reports enumerated five epidemics of dysentery, five of sweating sickness, (*quætie militiaire*), six of typhoid fever, and one of each of the following diseases,—catarrhal fever, bilious fever, intermittent fever, angina couenneuse, and measles.

Transmission of Syphilis from the Nurse to the Infant.

M. CUTLER read an essay which purposed to solve the problem of the law of the manifestation of consecutive symptoms of syphilis in the infant received from its nurse. This essay was divided into two categories of observations, the first consisting of five infected nurses, the children suckled by them remaining healthy. The second category comprised six observations of constitutionally infected infants whose nurses remained free from disease. From the critical analyses of these cases and of many others, the author concluded that syphilis may be communicated to infants equally with adults, and that the contrary opinion is founded upon defective observation, on oversight of certain indispensable details, and in many cases on the incomparably more rapid course of the disease in infants than in adults.

Treatment of Acute Rheumatism by Local Anæsthetics.

Dr. ARAN related the results of his researches on the application of anæsthetics to the joints, in acute rheumatism. A moist compress on which the agent is sprinkled is applied and renewed once in twenty-four hours, being enclosed by impervious bandages so as to prevent its evaporation. It is applied to each joint in succession as it becomes inflamed. Having experimented with various agents, Dr. Aran decides in favour of the *Dutch Liquid*. The relief afforded, as regards the local pain, is very decided, and lasts from one to six or eight hours according to the severity of the attack. The movement of the limbs is restored, and the swelling subsides, and the disease gradually declines in from six to eighteen days according to the duration and acuteness of the disease. The complications of rheumatism may be treated on general principles at the same time.

APOTHECARIES' HALL.

NAMES of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, 19th December, 1850:—William Sutherland; Nathaniel Clement Wood, Norfolk; James Hereford Jerwood; Robert Bolton; John Morton, Norfolk; Nathaniel Stenson Wood; Robert Bohun Kidd, Norwich; Robert Rooke France, Adelands; Alfred Beckett, Thame; John Gabriel French, Burton-on-Trent.

Hospital and Infirmary Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Fracture of the Spines of the Cervical Vertebrae—Partial Dislocation of the Axis on the Atlas—Death eleven days after the accident—Post-mortem examination.

JOHN JONES, a strong labouring man, was admitted Nov. 16, 1850, under Mr. Lloyd, with the following severe injuries, caused by a fall from a scaffold twenty feet high:—The scalp over the occiput was lacerated and bruised, and the bone exposed; there was a great deal of effusion of blood beneath the skin, rendering it tense at the back of the neck; and there was great tenderness in this region, especially over the fourth and fifth cervical vertebrae; any attempt to move the head was rigidly opposed by the action of the muscles; sensation and motion in the lower limbs, and a great part of the trunk, was completely lost; the paraplegia extended as high up as within two inches of the nipples; and no involuntary movements could be excited by irritating the legs: the motor power of the upper extremities was unimpaired, the breathing natural, the pulse 60; the pupils acted on exposure to light, he answered slowly when spoken to, and his countenance had a dull heavy appearance.

17th.—The paralysis of the lower part of the body continues, and is attended with priapism; the power of voiding urine is entirely lost; the movements of the right arm are now much impaired, and he says it feels numb; the skin is warm, the pulse 60, and labouring.—He was ordered some aperient medicine, and to be bled to 12 oz. from the arm; and to have the urine drawn off by a catheter.

18th.—The movements of the left arm are now impaired, as well as the right; and there is also diminished sensation in both, extending as far as the clavicles. The breathing is natural, the skin warm, the pulse 70, full and soft; the bowels have not been moved.—He was ordered an enema.

23d.—He has been placed on a water-bed on account of the appearance of redness and vesication on the heels and tuberosities of the ischium. The bowels were moved after several doses of aperient medicine; he has no power of retaining the motions; the paralysis, retention of urine, and priapism, continue the same.

24th.—His face is flushed, he sleeps a great deal, the respiration is rather laboured, the pupils are contracted, there is increased

warmth of the skin throughout the body, the pulse is 90, full and sharp, the sensation about the chest is more impaired.—Rep. V.S. ad 3xij.

26th.—The respiration is more laboured, and the breath escapes with a whiff from the corners of the mouth; he is continually dozing, his face is flushed and sunk, the skin hot and dry, the tongue parched and fissured, the pulse feeble and frequent, bowels relaxed; has had seminal emissions on the last two nights; the priapism and paralysis remain the same as before.—He died on the 27th at 5 P.M.

Post-mortem examination 22 hours after death.—There was fracture of the spines of all the cervical vertebrae except the first and last; the transverse ligament of the atlas was ruptured, and there was rupture of some of the ligaments in front of, and in connection with, the odontoid process, and partial dislocation of the axis from the atlas. The membranes were not ruptured, nor was there any blood effused within them. The spinal cord was congested and softened as low as the sixth dorsal vertebra.

Excision of Soft Cancer of the Breast.

M. K., æt. 55, a married woman, has had four children: discovered, four years ago, a small swelling, about the size of a pea, above the left nipple; it was not painful, but increased in size slowly until eighteen months ago, when she accidentally received a blow upon it, which was followed by the formation of an abscess in the tumor, a more rapid increase of its growth, and subsequently by occasional profuse discharges of blood from some slight abrasions on its surface. Admitted into St. Bartholomew's Hospital, Oct. 7, 1850, under Mr. Lloyd.

Both mammae were large: from the left, near the nipple, there projected a soft tumor, the size of a small orange, with an irregular nodulated surface, of a deep purple colour, and apparently highly vascular, covered by extremely thin skin, and presenting a few deep fissures about its centre, and connected at its base to the mammary gland. It did not give rise to much inconvenience. There were no enlarged glands in the axilla.—Tonics were prescribed, and a lead and opium lotion was applied to the breast: the lotion was afterwards changed for an application of conium.

After she had been in the Hospital a short time, the skin on the surface of the tumor ulcerated, and some deep fissures extended through its centre, from which a thin purulent and foul discharge issued. It occasionally bled freely.

Its removal was not recommended, but undertaken at her own urgent request: accordingly, on Nov. 21, Mr. Lloyd excised the diseased mass, together with the entire

mammary gland. On cutting through the tumor, it was found to be composed of a soft cancerous deposit in the interior of the mammary gland, differing in appearance from ordinary scirrhus of the breast, being of a pinkish colour, soft and friable, and having a defined margin. Some of the healthy structure of the mammary gland still remained around it.

Dec. 4th.—The wound is gradually healing, and the patient doing well.

*Femoral Hernia—Operation—Death—
Post-mortem appearances.*

Ann —, æt. 52, a thin emaciated woman: has been the subject of a femoral rupture two years, has never worn a truss, and has always been able to return the gut herself; but, on Nov. 23, was unable to do so, and was seized with violent pain in the abdomen, and vomiting. She took some aperient medicine, which failed to produce any natural action of the bowels; and on the following day, as the pain and sickness continued, she consulted a surgeon, who, in endeavouring to reduce the hernia, gave her a great deal of pain.

25th.—A portion of the intestine was returned into the abdomen; but the symptoms of strangulation, though somewhat less severe, still continued, and in the afternoon she came to St. Bartholomew's Hospital, and was admitted under Mr. Lawrence. She was much exhausted, and had an extremely anxious appearance. The tongue was furred, the pulse quick and very feeble; the abdomen was tense, distended with flatus, and intolerant of pressure; the rupture was rather soft, about half the size of a pigeon's egg; the skin over it was red, and she said it was not so tender as it had been; she had passed no motion since the morning of the 23d; and she continued to vomit frequently a dark-brown offensive fluid.

The condition of the patient, and the too great probability that the intestine had already suffered severely from tight constriction, rendered it necessary that an operation for its relief should be performed without delay. Owing to the very feeble state of the pulse, no chloroform was given. Mr. Lawrence divided the coverings of the hernia in the usual way, and, on opening the sac, some dark fluid escaped: the stricture was so tight, that a small director was introduced beneath it with difficulty; the intestine was very dark, but smooth on its surface, and had not lost its vitality, and was therefore returned into the abdomen on the division of the stricture. After the operation the vomiting ceased and the pain was relieved: the patient, however, did not rally, and died at 5 p.m. on the 26th.

Post-mortem examination.—The intes-

tines were covered by a recent layer of lymph, and there were about six ounces of turbid fluid in the abdomen: a small oval portion of the wall of the ileum, including the greater portion but not the entire circumference of the gut, had formed the contents of the rupture; was of a dark livid colour, had lost its smoothness on the peritoneal surface, and was surrounded by a deep mark caused by the stricture. The mucous membrane in the interior of this portion of the intestine was soft and pulpy, and presented a line of superficial ulceration corresponding to the situation of the mark caused by the stricture on the peritoneal surface of the intestine. Two inches of the intestine above this point were also dark and discoloured, but in a less degree, and had most probably formed the additional contents of the rupture when the symptoms commenced, and was that portion which was returned on the 25th, before her admission.

Correspondence.

CONVENTION OF POOR LAW MEDICAL OFFICERS.

SIR,—The Committee have reason to believe that Lord John Russell has expressed a desire to obtain information on the subject of Poor Law Medical Relief, and that he entertains opinions favourable to the objects of the Convention; they have, therefore, with the view of improving this auspicious indication, determined to seek an interview by Deputation, in order to present to his Lordship a Memorial setting forth the grievances under which the Union Surgeons labour. Should an interview be granted, the Committee purpose inviting those Members of Parliament, who have already taken an interest in the subject, to accompany the Deputation, and also Delegates from Provincial Medical Societies.

It is hoped that all in the Profession who have access to Members of Parliament will immediately draw special attention to the subject, in order to secure their co-operation in the objects of the Memorial.

The Committee trust that by a direct appeal to his Lordship they may induce him to call the attention of the President of the Poor Law Board to the evils complained of, so that an amelioration of the present system may be effected, or, if necessary, that the President be advised to seek from Parliament an extension of power, to enable him to amend the regulations under which medical relief is now administered through the Poor Law Board.

Your obedient servant,

C. F. J. LORD, Hon Sec.

4, Hanover Square,
December 23, 1850.

Medical Intelligence.

THE RAVAGES OF THE CHOLERA AT KINGSTON IN JAMAICA.

THE latest accounts brought from Jamaica were up to the 14th November, and from them we find that the Cholera has prevailed in a most severe form in the chief towns of the Colony. It first appeared in Port Royal, where it has now almost entirely disappeared, having previously cut off *a fourth of the entire population*. In Kingston the havoc was frightful; so great indeed, that the faculty had ceased to report it officially to the Board of Health. Some say that the absence of official information is owing to the inability of the medical gentlemen to ascertain the precise number of deaths, whilst others attribute it to a prudent disinclination to excite further the public mind. The whole community were panic-stricken. In one day the interments reached 203; indeed, on very good authority, they are said to have greatly out-numbered even this, but we refrain from supplying figures in the absence of authentic information. To add to the terror, it was made known that the most requisite medicines were not in the island, or rather that the supply had become suddenly exhausted. Immediately on representation of this being made to Commodore Bennett, at Port Royal, he dispatched a vessel of war, the Alban steamer, to St. Jago de Cuba, and in less than 60 hours she had returned with the supply. The Board of Health were doing the utmost in their power to administer to the relief of the afflicted, and to provide for the destitute, whose poverty rendered them a ready prey for the plague. Hitherto the mortality was confined to the districts of the poorer classes, but during the few days prior to the packet's leaving, its spread appeared more general, although, perhaps, in some cases in a milder form. In addition to the exertions of the Board of Health, which is composed principally of the clergy and the faculty, the merchants of Kingston had formed a benevolent society, and were most actively engaged in doing all that humanity could dictate in so trying an emergency. On the morning of the packet's departure things hardly looked so gloomy, and it is said that during the previous day and night the dead-carts had had a rest.

Wretched and desponding as is the description we have given above of Kingston, our accounts represent the state of St. Catherine's, the seat of Government, as far more distressing. There, although the actual number of deaths did not amount to those in Kingston, still, in proportion, the

mortality had been greater. Entire families had been seized with death by the merciless destroyer. At one period, it is said, on the best authority, there were lying at the burial places 70 bodies confined without a person to inter them, and but for the judicious conduct of Sir Charles Grey, the Governor, it is hard to state what might have been the consequence. His Excellency ordered the painful work to be performed by 20 of the convicts of the district prison, who did it on condition of their sentences being commuted. On another occasion his Excellency, it is reported, caused some of the troops to perform a similar task.

In the country parishes, too, the scourge was extending itself rapidly. Our information is derived from the very best private sources. Metcalfe, of all the out-parishes, may be said to have been the most distressed, and in the entire parish there was but one doctor. In other parishes there were no medical men. St. Andrew's parish, which joins immediately on Kingston, had lost large numbers of its inhabitants. In Metcalfe, as in many other parishes, the greatest difficulty was felt in procuring people to bury the dead. On the north side every precautionary step was being taken. One case, not fatal, had appeared in Trelawny. Wednesday, the 13th of November, was observed in Kingston, St. Andrew's, St. Catherine's, and Port Royal, as another day of prayer and humiliation, in consequence of the day appointed by the Governor (Nov. 1) being a most unpropitious one.

As might well be expected, business was entirely "at a standstill"—every department was most unsettled. In Spanish Town, at one period, most of the places of business were closed, being without servants and attendants, who had either died or had deaths within their families.

In Kingston the heat during the day was oppressive—the mornings and evenings were more pleasant; the rains appeared to have ceased entirely. Almost daily, heavy black clouds overhung the town, but up to the departure of the steamer no rain had fallen for some days.

Private letters state that it is impossible to convey an idea of the excitement and alarm which prevail, or of the gloomy appearance of Kingston—indeed, of the whole island. In the few parishes where the scourge had not made its appearance, prompt sanitary regulations were being made. There were a few other deaths besides those from cholera.

The intelligence by the last mail from Jamaica, which extends to the 28th of November, is quite as gloomy as that above given. The cholera had abated in Kingston

very much, and might be said entirely to have disappeared from Port Royal and Spanish Town, but it had appeared in a most malignant form in almost every other part of the island. In the mountain districts the mortality was fearful, but there existed no possibility of ascertaining accurately the number of victims. In consequence of the spread of the epidemic the House of Assembly had suspended business until the 10th of December: they reassembled on the 19th of November with barely a quorum present.

THE PROSPECTS OF PHARMACY. RETURN OF MR. JACOB BELL FOR ST. ALBAN'S.

It is with satisfaction we announce that Mr. Jacob Bell, well known as the Editor of the *Pharmaceutical Journal*, has been returned member for Saint Alban's, by a majority of 129. We think that the introduction of this gentleman into the House of Commons will be beneficial to the interests, not only of those whose rights he has specially and ably advocated—namely, Pharmaceutical practitioners, but of the medical profession in general. We may anticipate from the exertions of the honourable member some good results in reference to a Medical Reform Measure, and the proposed separation of drug-dealing from medical practice: also a Restriction of Sale Poisons Bill, and other subjects of which the very large proportion of lawyers, merchants, and magistrates, who now occupy the Benches of the House, have no practical knowledge.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 20th inst.:—A. Carson; R. Wall; R. Sproule; T. J. E. Brown; R. Roberts; T. J. Jones; J. Gibson; N. W. Jones; J. Meane; S. Hudson; and T. B. Brindloss.

BOOKS & PERIODICALS RECEIVED FOR REVIEW

DURING THE LAST THREE WEEKS.

University Reform: Letters to the Right Hon. the Earl of Aberdeen. By A. Kilgour, M.D.

The Boston Medical and Surgical Journal. October and November, 1850.

Lectures on Clinical Medicine. By J. H. Bennett, M.D. F.R.S.E. &c.

New York Journal of Medicine. Nov.

The New York Register of Medicine and Pharmacy. Nos. 4 and 5, November and December 1850.

Journal de Chimie Médicale. Decembre. Comptes Rendus. Nos. 21 and 22, 18th and 25th November, 1850.

BIRTHS & DEATHS IN THE METROPOLIS

During the Week ending Saturday, Dec. 21.

BIRTHS.		DEATHS.	
Males....	720	Males....	564
Females..	748	Females..	602
1477		1166	

CAUSES OF DEATH.

ALL CAUSES	1166
SPECIFIED CAUSES	1166
1. Zymotic (or Epidemic, Endemic, Contagious) Diseases....	231
<i>Sporadic Diseases, viz.—</i>	
1. Dropsy, Cancer, &c.	48
2. Brain, Spinal Marrow, Nerves, and Senses	149
4. Heart and Bloodvessels.....	31
5. Lungs and organs of Respiration	274
6. Stomach, Liver, &c.	50

Hydrocephalus.....	25		
Apoplexy.....	34	Childbirth.....	8
Paralysis.....	19	Uterus.....	1

REMARKS.—The total number of deaths was 20 above the average mortality of the 51st week of ten previous years.

METEOROLOGICAL SUMMARY.

Mean Height of the Barometer 29.41
 Thermometer " 28.6
 Self-registering do. " Max. 0.0 Min. 9°
 From 12 observations daily. Sun.

RAIN, in inches, .71.—Sum of the daily observations taken at 9 o'clock.

METEOROLOGICAL.—The mean temperature of the week was 1° below the mean of the month.

NOTICES TO CORRESPONDENTS.

The Vichy Waters.—"A." We do not know.—"B." Apply to Baillière, 219, Regent Street.
 Dr. T. G. Melhuish's interesting remarks on Human Gestation will be inserted in an early number.

The communications of Dr. Fleming and Dr. O'B. Bellingham have safely reached us. The papers shall, if possible, be inserted in the first number of the new volume.

Mr. Herbert Williams.—We will take an early opportunity of publishing the Bill, or such parts of it as require publication. Our next number is already filled according to engagements previously entered into.

INDEX TO VOL. XI. OF THE NEW SERIES.

Abdomen, Dr. Gordon's case of homicidal wound in the, 24.

Abortionism, criminal, in New York, 487.

Abscess of the liver, Mr. Paterson's case of, 771.

Absorption of insoluble substances, 36.

Absorption, experiments on, 908.

Academy of Medicine, Paris, proceedings of the:—M. Huguier on disinfecting liquids, 35; M. Gosselin on synovial cysts of the wrist, 35; M. Orfila's medico-legal researches on dried cerebral substance, 78; influence of vaccination on population, 79; epidemic dysentery of Mortagne in 1849, 118; alkalinity of the human blood, 118; Dr. Bucquoy on the coexistence of sweating sickness and cholera, 161; M. Gerdy on the intellectual powers of deaf-mutes, 161; Dr. Honoré on turning in cases of deformed pelvis, 162; M. Drouard on fracture of the temporal bone, 162; new speculum for the mouth, 246; gutta percha instruments, 246; M. Andral on the state of the joints in acute rheumatism, 394; M. Martinet on the application of electricity in diagnosis, 394; M. Civiale's case of disease of the urinary organs, 340; M. Lecanu on the preparation of pills of iodide of iron, 340; M. Desmarres on cholesteritis, 589; M. Lassaigne's chemical tests of cerebral matter, 589; M. Roux's case of extirpation of a bronchocele, 589; M. Piorry on the use of chloride of sodium in ague, 589; Dr. Chretien's case of vicarious hemorrhage from the integuments of the face, 643; Dr. Cabaret's case of extirpation of a bronchocele, 643; M. Gerdy's case of extirpation of the astragalus, 644; M. Danyau on the influence of ergot of rye on fetal life, 680; Dr. Delfraysee on the causes of the failure of vaccination, 728; M. Guérin on the functions of the bulb of the urethra, 729; M. Landouzy on nephritic amaurosis, 772; M. Le Goin on the inhalation of carbonic acid in phthisis, 772; M. Wanner on the etiology of tubercularisation, 773; Dr. Bernier on arsenic and *Adansonia digitata* in intermittent fever, 814; M. Bouchet on the employment of zinc in painting, 814; M. Chartroule on iodine vapour in phthisis, 814; Dr. Rendu on foreign bodies in the

air-passages, 942; Dr. Aran on local anæsthetic medication, 986; M. Sestier on oedema of the larynx, 987; M. Bonnard's case of extraction of a calculus from the prostatic portion of the urethra, 987; Dr. Mayer on scarification of the neck of the uterus in leucorrhœa, 1081; M. Latour on the employment of impermeable varnish in inflammations of the skin, 1031; M. Roux's case of aneurismal varix, 1032; M. Borelli on injections in the treatment of encysted tumors, 1051; electro-physiological researches on the functions and endowments of the chorda tympani, 1106; M. Levret on the treatment of gout and rheumatism, 1106; M. Cullierier on the transmission of syphilis from the nurse to the infant, 1106; Dr. Aran on the treatment of acute rheumatism by local anæsthetics, 1106.

Academy of Sciences, Paris, proceedings of the:—Dr. Charpentier on the diet of the miners of Charleroi, 80; M. Quatrefages on some points in the history of the fecundation of the lower animals, 80; M. Roux on staphylophraphy, 118; M. Pouillet on electrical phenomena, 142; M. Clement's analysis of the blood of animals after acute suffering, 162; M. Valette's proceeding for the radical cure of inguinal hernia, 163; M. Legrand on a new mode of removing wens, 210; M. Jomard's antidotes for the bites of serpents, 247; veterinary surgery, 247; M. Ghatin on the general diffusion of iodine, 547; M. Fourcault on a new application of apparatus termed hydrophora, 589; M. Serres on the phosphine or luminous spectra produced by compression of the globe of the eye, 589; M. Robin on the poisonous action of agents productive of dead animal matter against spontaneous combustion, 590; M. Sedillot on staphylophraphy, 644; M. Martinet on the phenomena of phosphene, 644; M. Chassaiguac's case of ligature of the common iliac artery, 644; M. Becquerel on the employment of mercurials in typhus fever, 661; M. Payen on the presence of casein in the blood, 683; M. Chevallier on the diseases of persons employed in the manufacture of quinine, 729; M. Landouzy on, 773; M. Bernard's experimental researches on

- the woorara poison, 773; caseine in the blood of women during lactation, 774; M. Coste's researches on human gestation, 814; M. Bernard on the formation of sugar in the liver, 815; M. Dujardin on the nervous system of insects, 815; M. Serres on phosphene in its relations to myopia and presbyopia, 856; M. Stas on the composition of the liquor amnii and allantois, 857; M. Bourguignon on contagion and treatment of scabies, 943; M. Augend on a new property of chloroform, 943; Dr. Dezauliers on the production of images on the retina, 944; M. Brown-Sequard on the transmission of sensitive impressions in the spinal marrow, 988; M. Serres on the employment of cold douches in the lymphatic temperament, 988; M. Auzias-Turenne on syphilitic inoculation, 989; M. Landouzy on exaltation of the sense of hearing in paralysis of the facial nerve, 989; M. Bazin on scabies, 989; M. Lassaigue on the action of the pancreatic juice on oils, 1033; M. Robin's researches on disinfecting liquids, 1033;

- Cramps, violent, caused by green tea, 84.
- Crompton's, Mr. D. W. cases and observations in surgical practice, 830.
- Curling's, Mr. T. B. case of induration of the sterno-cleido muscles in young infants, 880.
- Curtis, Mr. and Dr. Pearson, on the poisonous properties of lobelia inflata, 285.
- Curiosity, a surgical, 559.
- Dalrymple, Mr. on the pathology of the human eye, reviewed, 769.
- Dalton's, Dr. conclusions regarding the elimination of iodine by the kidneys, 885, 932.
- Danyau, M. on the influence of ergot of rye on foetal life, 680.
- Davey's, Dr. contributions to mental pathology, reviewed, 886.
- Death, Dr. Dowler on the signs of, 478.
- Death from poisonous fungi, 307.
- Debout, M. on umbilical puncture in ascites, 912.
- Decadence of the profession in the United States, 1066.
- Deformities, Mr. Lonsdale on some of the more practical points connected with the treatment of, 359, 617.
- Delirium and coma, Dr. Todd's lectures on the treatment of, in sequel to the Lumbian lectures for 1850:—
- LECT. 4.—Termination of two cases of pneumonia reported in the last lecture; delirium of bronchitis; treatment of rheumatic and gouty delirium; cases; the delirium of erysipelas; nature of erysipelas; treatment; means of prevention of the delirium; case; advantage of the stimulant treatment in preventing secondary deposits; cases; sudden coma and death in erysipelas; cases, 69—74.
- LECT. 5.—Treatment of the delirium of scarlet fever and other exanthemata; the delirium of typhus or typhoid fever; two forms; nature of typhus fever; outline of its treatment; use of stimulants; local treatment in the delirium; blisters; Dr. Corrigan's plan; use of opium; Dr. Graves' plan of tartar emetic and opium; treatment of hysterical delirium; case; use of opium; restraint; treatment of puerperal delirium; prognosis; case, 109—114.
- LACT. 6.—Hysterical delirium in men; treatment of epileptic delirium; diagnosis of epileptic delirium; epileptic delirium a prolonged epileptic paroxysm; can it be cut short? bleeding; moral treatment; treatment of coma; diagnosis of apoplectic coma; treatment of traumatic coma, of epileptic coma, and of the other varieties of coma, 133—137.
- Delfrayse, M. on the causes of the failure of vaccination, 729.
- Denonvilliers, M. case of imperforation of the rectum, 304.
- Desmarres, M. on cholesteritis, 589.
- Despretz, M. on the congelation of protoxide of nitrogen and alcohol, 139.]
- Dezauliers, M. on the production of images on the retina, 944.
- Diabetes, case of, from an overdose of nitrate of potass, 154.
- Diabetes mellitus in a child, case of, 689.
- Discoveries, scientific, and improvements, publication of, 669.
- Disinfecting liquids, Mr. Huguier on, 35.
- Douglas, Dr. on the influence of hypertrophy and dilatation on diseases of the heart, reviewed, 589.
- Dowler, Dr. on the signs of death, 478.
- Downing, Dr. T. C. on tic douloureux and other painful affections of the nerves, reviewed, 303.
- Drouard, Dr. on fracture of the temporal bone, 162.
- Drowning, Dr. Riedell on the post-mortem appearances of death by, 478.
- Druitt's, Mr. surgeon's vade-mecum reviewed, 977.
- Duchenne, Dr. on palsy, reviewed, 807.
- Duffin's, Mr. history of a successful case of ovariectomy, 893.
- Dulcamara, case of poisoning with, 548.
- "Dumb-bell" crystals, Dr. Golding Bird on the nature and characters of, 700.
- Duplay's Dr. case of cerebral hæmorrhage, 942.
- Durham, County Medical Association, 247.
- Durwell, M. on the employment of forced flexion for arresting hæmorrhage by wounds of the palmar arch, 351.
- Dyce Sombie, Dr. Mayo on the case of, 123.
- Dysentery, epidemic, of Montague in 1849, and its relations to epidemic cholera, 116.
- Eclampsia and albuminuria, on the coincidence of, 874.
- EDITORIAL ARTICLES:—State of health in

- the metropolis compared with that of 1849, 26; Apothecaries' Society—the apprenticeship system, 108; the plea of insanity, 152; the railway accidents bill, 200; the College of Surgeons in England and Scotland, 239; explosions in coal mines, 240; medical evidence in cases of insanity, 240; the case of Ann Merritt, 291; the general practitioners' bill, 334; the lobelia quackery in Cumberland; 370; fees to medical witnesses at coroners' inquests, 415; toleration of manslaughter by unlicensed practitioners, 455; convention of poor-law medical officers, 502; the medical session of 1850-51, 542; the Sydenham Society, 543; correspondence between Sir George Grey and the Royal College of Surgeons, 580; insurance offices and the medical profession, 632; medical education in the United States and in the European medical schools, 670; inquests in Middlesex, 715; homœopathic practice and slow poisoning by lead, 717; process of refining sugar by salts of lead, 755, 801, 836; anæsthetic robberies, 758; parliamentary report on prison discipline, 881, 932, 973; annual report of the Commissioners of Lunacy, 1021; comparative mortality in the London hospitals, 1069; remarks on the conclusion of the volume, 1101.
- Electricity, M. Martinet on the application of, in diagnosis, 304.
- Epidemiological Society, objects of the, recently founded, 28; general meetings of, 171, 307; Dr. Babington's speech on posing the establishment of the, 473; contemplated arrangements of the, 766; meetings of the, 903.
- Epps, Dr. on homœopathy and its principles, review of, 301.
- Ergot of rye, M. Danyau on the influence of, on fœtal life, 680.
- Erichsen, Mr. election of, to the professorship of surgery in University College, 87.
- Esdaile, Dr. on the operation for the removal of scrotal tumors, with a comparison of the effects of mesmerism and chloroform, 449.
- Ether, advantages and disadvantages of, as an anæsthetic, 805.
- Ether and chloroform, caution in the use of, 505.
- Ether vapour, proposed exhibition of, to the dying, 383.
- Every-day wonders, or facts in physiology which all should know, review of, 460.
- Explosions in coal mines, editorial observations on, 240.
- Faraday, Dr. on the magnetic properties of oxygen gas, 953.
- Farquharson's Dr. case of poisoning by the seeds of *jatropha curcas*, 616.
- Fearnside, Dr. on the treatment of the warty ulcers of Marjolin by chloride of zinc, 411; illustrations of pancreatic disease, 967.

- Fife's, Sir John, case of osteo-sarcoma of tibia and fibula, 117.
- Fillon, M. on hæmatozoa, 462.
- Fluorine in blood and milk, 392.
- Forceps, new, to supersede Museux's, 79.
- Forget's M. case of tumor difficult of diagnosis, 942.
- Fourcalt, M. on a new application of apparatus termed hydrophora, 589.
- Fownes', Mr. manual of chemistry, reviewed, 29.
- Fracture of the tibia, Mr. Tamplin's case of, of twenty-four years' standing, successfully treated, 140.
- Fracture of the inferior extremities, Mr. J. W. D. Brown on a new apparatus for, 550.
- Fracture of the neck of the humerus, 590.
- Fresenius's, Dr. instruction in chemical analysis, reviewed, 890.
- Gallwey's, Mr. M. Broke, essay on unhealthy inflammations, 405, 494, 624, 706, 789, 1009, 1096.
- Galloway's, Mr. manual of qualitative analysis, reviewed, 892.
- Galvanic current, velocity of the, in the electric telegraph, 977.
- Garrod's, Dr. case of diseased bone and teeth, 896.
- General practitioners' incorporation bill, 171.
- General Board of Health, appointments at the, 350.
- General practitioners' bill, editorial observations on its probable influence on the medical reform question, 334.
- General Hospital, Nottingham, election of surgeon to the, 953.
- Geoghegan, Dr. on the morbid appearances in arsenical poisoning, 171, 216.
- Geological Society, papers to be read at the, 1041.
- Gérardin's, M. report on cholera in packet ships, 209.
- Gerdy, M. on the intellectual powers of deaf-mutes, 161; case of extirpation of the astragalus, 644.
- Gerlach's, Dr. compendium of anatomy reviewed, 75.
- German Hospital, Dalston, report of the, 41.
- Gestation, Mr. Kesteven on the presentation of the back at the full period of, 414.

- Girdlestone's, Mr. case of partial dislocation of the radius and ulna backwards with the formation of a new joint, 158.
- Gladstone, Dr. on the growth of plants in abnormal atmosphere, 423.
- Glairine, M. Bonjean on the presence of, in mineral waters, 603.
- Glanders, chronic, case of, in man, 315.
- Glasgow Faculty, an act for better regulating the principles of the Faculty of Physicians and Surgeons of Glasgow, 85.
- Goin, M. le, on the inhalation of carbonic acid in phthisis, 772.
- Gordon's, Dr. case of homicidal wound in the abdomen, 24.
- Gosselin, M. on synovial cysts of the wrist, 35.
- Granville, Dr. "The Sumbul," reviewed, 245.
- Grantham's, Mr. case of two calculi in the bladder, 232.
- Graham's, Professor, Elements of Chemistry, Part 4, reviewed, 801.
- Gray, Mr. on the development of the retina and optic nerve, reviewed, 679.
- Greaves', Dr. experiments on the action of sulphite of lead on dogs, 856.
- Gregory's, Dr. observations on the sulphite of lead, 379.
- Gregory's, Dr. translation of Baron von Reichenbach's researches on magnetism, electricity, &c. reviewed, 585.
- Griffith, Dr. on the crystals of oxalate of lime occurring in the urine, 1091.
- Gubler's, M. case of malformation of the hands, 452.
- Guérin, M. on the functions of the bulb of the urethra, 729.
- Gull, Dr. on the treatment of anasarca by incision, 553.
- Gun-shot wounds of the thorax, Mr. R. H. A. Hunter on the frequency of the escape of the lungs in, 713.
- Gutta-percha instruments, 246.
- Guy's Hospital: lacerated wound of forearm from the bursting of a cannon, 1034; gun-shot wound in neck, 1037.
- Hæmorrhage, arrest of, by matico, 337.
- Hæmorrhage, fatal, from the umbilicus, in new-born children, 321.
- Habnemann, the, hospital, and its supporters, 599.
- Hall's, Dr. Marshall, memoirs on the nervous system, reviewed, 804.
- Hamilton's, Dr. W. remarks on the vital statistics of the borough of Plymouth, 528, 568, 611, 665, 905.
- Hancock, Mr. on the operation for strangulated hernia, reviewed, 29.
- Hardships of young physicians, 301.
- Hare's, Dr. remarks on the mortality in hospitals, 897.
- Harveian Society, office-bearers for the present session, 731.
- Harveian Society, proceedings of the:—Dr. Powell on a fatal case of carcinoma of the ilium, 1029; on carcinoma of the right lung, 1029.
- Harveian oration, by Dr. Wilson, 41.
- Harvey, Mr. George, on the induction of premature labour, 98.
- Hassall, Dr. on the cause of the green colour of the water of the Serpentine, 86.
- Hassall, Mr. on the colouration of water by algæ, 259.
- Hastings and Carswell, Drs. the honour of knighthood conferred on, 84.
- Hawkins's, Mr. case of strumous disease of the os calcis, 808.
- Hawkins, Mr. Charles. letter from, respecting the "Brodie testimonial," 644.
- Hayward, Dr. on the comparative value of different anæsthetic agents, reviewed, 768.
- Heart, Dr. Bellingham's lectures on diseases of the:—
- LECT. 8 (concluded).—EXAMINATION OF THE HEART IN DISEASE (continued): fremitus cœtare, or purring tremor; circumstances under which fremitus cœtare is felt; cause of fremitus cœtare; signs furnished by percussion; alterations in the extent and degree of the heart's superficial dulness; conclusions respecting percussion of the præcordial region, 153—158.
- LECT. 9.—Signs furnished by auscultation; alterations in the intensity and tone of the sounds of the heart; alterations in the duration of the sounds of the heart; alterations in the limits within which the sounds of the heart are audible; alterations in the frequency of the sounds of the heart; alterations in the rhythm of the heart's sounds; alterations in the number of the heart's sounds, 221—225.
- LECT. 10.—Abnormal sounds developed during the heart's action; pericarditic friction-sounds; endocardial or valvular murmurs; bruit de soufflet; circumstances under which bruit de soufflet is heard; conditions under which bruit de soufflet is developed; mechanism of production of bruit de soufflet; bruit de soufflet at the right side of the heart; conclusions from the presence of bruit de soufflet, 309—315.
- LECT. 11.—Abnormal sounds developed during the heart's action; sawing, fling, and grating valvular murmurs; conclusions from the presence of a rough valvular murmur; musical valvular murmurs; arterial murmurs; arterial bruit de soufflet; rough or grating arterial murmurs; venous murmurs; continuous venous murmur; musical venous murmur; seat of the continuous and musical murmurs; mechanism by which they are produced, 397—404.
- LECT. 12.—General signs of cardiac disease; countenance in heart disease; position of the patient; palpitation; pal-

- pititation depending upon organic disease; palpitation independent of organic disease of the heart; characters by which the palpitation depending upon organic disease of the heart is distinguished from that which occurs independent of organic disease; immediate cause of palpitation; influence of the coronary circulation, 561—567.
- LECT. 13.**—The pulse as a means of diagnosis in cardiac disease; morbid conditions of the heart which give rise to varieties of the pulse; influence of the quality and quantity of the blood; pulse in hypertrophy, and in dilatation of the left ventricle; pulse in aortic regurgitation; cause of the jerking pulse; intermission, irregularity, and inequality of the pulse; pulse in contraction of the mitral orifice, and in regurgitation through this orifice; pulse in contraction of the aortic orifice; pulse in fatty degeneration of the heart; summary of the principal varieties of the pulse, 691—696.
- LECT. 14.**—Indirect or secondary symptoms; congestion; causes of; mode of production of; organs in which congestion most readily occurs; effects of congestion upon different organs; congestion of the lungs; œdema of the pulmonary tissue, 867—871; Indirect or secondary symptoms of heart disease (continued); dyspnoea; starting in alarm from sleep; cough; hæmoptysis; pulmonary apoplexy, 953—960.
- LECT. 15.**—Indirect or secondary symptoms of cardiac disease (concluded); congestion of the liver; congestion of the intestines; epigastric pulsation the result of gastro-intestinal congestion; epigastric pulsation in nervous, hysterical, and anæmic subjects; congestion of the brain; influence of hypertrophy of the left ventricle in giving rise to apoplexy or paralysis, 1043—1049.
- Health, editorial remarks on the state of, in the metropolis, in 1850, compared with that of 1849, 27.
- Heat, effect of, in expanding metals, 729.
- Herapath, Mr. on slow poisoning by lead, 518.
- Hernia, femoral; operation for, 81.
- Hewitt's, Mr. Prescott; case of crude tubercle in the medullary cavity of the femur, 808, case of aneurism of the mitral valve, 980.
- Hillier, Mr. on gout, reviewed, 892.
- Hogg, Mr. on the management of infancy, reviewed, 888.
- Holland, Dr. on consumption and indigestion, reviewed, 1025.
- Homœopathic practice, and slow poisoning by lead, 717.
- Homœopathic hypotheses, and chronic poisoning by lead, 949.
- Homœopathy in New York, 199.
- Hooker's, Dr. William, practical view of the mutual duties, &c. of the medical profession and the community, 678.
- Honoré, Dr. on turning in cases of deformed pelvis, 162.
- Honours conferred on Drs. Hastings and Carswell, 84.
- Honours conferred on medical men in the army and navy, 346.
- Hooping-cough, coffee a remedy for, 170.
- Hôpital de la Charité, Paris, reports from the:—M. Rayer on a case of pneumothorax, 993.
- Hospitals, Roman, 595.
- Houghton, Mr. on life-assurance certificates, 729.
- Huguier's, M. case of fibrous polypus of the rectum, 210.
- Huguier's, M. case of cataneous affection of doubtful character, 209.
- Hughes's, Dr. case of ventral extra-uterine pregnancy, 539.
- Hunter, Dr. on the relative frequency of the pulse at different elevations, and at different periods of the day, 256.
- Hunter, Mr. R. H. A. on pulmonary diseases in tropical climates, 367, 578; on the frequency of the escape of the lungs in gun-shot wounds of the thorax, 713; on cardiac and aortic diseases, 875; on mercury in syphilitic eruptions, 941.
- Hydrocele, analysis of the fluid of, 755.
- Incrustation of steam-boilers, on the removal of, 600.
- Inflammation, Professor Paget's lectures on, delivered in the theatre of the College of Surgeons, 1, 89.
- Inflammations, unhealthy. Mr. M. Broke Gallwey on, 405, 404, 624, 706, 789, 1009.
- Inquests in Middlesex, editorial observations on, and on fixed salaries to coroners, 715.
- Inman, Dr. on the occurrence of starch granules in the urine, 879; on the detection of seminal fluid in the urine in cases of masturbation, 925.
- Iodine, on the period at which it appears in the urine, 871.
- Iodine, Dr. Dalton's conclusions regarding the elimination of, from the kidneys, 885.
- Iodide of potassium, employment of, in cigars for consumptive patients, 660.
- Insanity, Dr. Jamieson on the medical jurisprudence of:—
- LECT. 1.**—On the relation of insanity to certain allied conditions; resemblance of insanity to dreaming, febrile delirium,* and delirium tremens; these occasional causes of the disease; excited passion and insanity; psychological character of insanity; insanity contrasted with illusion. hallucination, delusion, disease with mental symptoms, intellectual dullness, eccen-

tricity, abased fancy, and moral depravity; pathology of insanity, 177—182.

LECT. 2.—Medico-legal authority in insanity; civil consequences of the state; legal subdivisions—idiocy, lunacy, unsoundness of mind; legal doctrines; medical classification; (a) general insanity; 1 amentia, 2 mania, 3 dementia; (b) partial insanity; 1 monomania, 2 moral insanity; relation of the foregoing states to each other; doubtful and variable cases; general description of the insane state; the relation of country, age, sex, station, temperament, and social condition, to disease of the mind; (a) moral condition of lunatics; premonitory moral disorder; the emotional features of insanity, selfishness, &c. 265—271.

LECT. 3.—General description of the insane state (continued); (a) the moral condition of lunatics (concluded); their selfishness, suspiciousness, timidity, and apathetic listlessness; (b) the intellectual condition of lunatics manifested in deranged voluntary power over the succession of thoughts, in delusion, imbecility, incoherence, and extravagant conduct; disturbed relation of will to thought; delusions; their origin in violent mental impressions; their hold on the belief; their resistance to interfering doubts; their absorption of the attention most distinctly defined in monomania; concealed delusion; delusions an insufficient test of unsoundness; divided into high and low; subjects of exciting delusions; their insufficiency to produce happiness; subjects of depressing delusions; thanatophobia; panphobia; hypochondriacal monomania; demonomania, &c.; relative frequency of high and low delusions; modifications by sex, temperament, education, and bodily disease, 333—338.

LECT. 4.—General description of the insane state (continued); (b) intellectual condition of lunatics (continued); imbecility of mind; manifested in various habits and actions; exemplified; imbecility in thinking exemplified in writing; intellectual disorder increases with the prolonged effort at control; a lunatic's views of the insane conduct of other lunatics; may be aware of his legal position; the characteristics of lunatic epistles; exemplification of the expression of delusion; incoherence not a form of insanity, but a possible symptom in any form of the disease; best marked in mania and dementia; incoherence in monomania; extravagance of conduct; the result of delusion; exemplified; motives not traceable in insane actions; criminal deeds of the insane not indicative of viciousness; unsuitableness of insane actions to proposed object, 439—445.

LECT. 5.—General description of the

insane state (continued); (c) insane impulses; (1) the suicidal impulse; suicide amongst the insane; its lunatic characteristics; medico-legal consideration of suicide; *felo-de-se*; legal consequences; self-murder, insane suicide, and suicidal moral insanity; circumstances of these contrasted; suicide from suggestive opportunity, fascination, imitation, &c.; When is suicide to be deemed an act of insanity; legislation on the subject of suicide; (2) the homicidal impulse; medico-legal consideration of homicide; insane homicide and homicidal moral insanity; Reil's description of a paroxysm of mania without delirium; delirium in agendo; Criminal homicide and insane impulse contrasted; When is homicide to be deemed an act of insanity? connected delusion; contemporaneous delusion; consecutive delusion; moral insanity, 521—527.

LECT. 5.—General description of the insane state (concluded); (c) insane impulses (concluded); (3) the impulse to steal; a symptom in insanity; sometimes a form of insanity; kleptomania; distinguished from criminal theft; (4) the impulse to burn; sometimes a form of diseased mind; pyromania; its characteristics; (5) the impulse to intoxication; medico-legal consideration of drunkenness; legal relations of drunkenness; modifications in practice; the propensity to intoxication sometimes a disease; dipsomania; legislation on the subject of drunkenness; (6) morbid sexual impulse; cytheromania; (7) unnatural impulses; (d) physical condition of lunatics; physiognomy of the insane; the insane expression; the eye; the mouth; the ear; the complexion; the bodily physiognomy; automatic movements, &c.; odour; muscular power and endurance; insensibility to discomfort; pulse; post-mortem appearances; feigned insanity, 647—653.

LECT. 7.—When is mental aberration such as to justify its being deemed insanity? discrimination of acute and maniacal delirium; directions for the examination of the insane; special difficulties; lunacy certificates; Scottish lunacy law asylums, and form of certificate; proceedings under the English Lunacy Act; form of certificate; When is mental unsoundness such as to justify interdiction? interdiction defined; Scottish and English mode of procedure; grounds of interdiction; testamentary capacity of the insane, 760—766.

LECT. 8.—Testimonial capacity of lunatics; civil responsibility in reference to contracts, marriage, &c.; When does insanity justify coercion? cases which do not demand the restraint of an asylum; superintendence always requisite; lucid

- intervals; how judged of; recovery; the marks of recovery; discharge of lunatics; liberation and emancipation; criminal responsibility of the insane; legal test; consciousness of right and wrong; power of self-control; insufficiency of the legal test; evidence of irresponsibility; how sought to be obtained; medical opinion; how dealt with in law-courts and by the press; insufficiency of ordinary juries to determine upon insanity; necessity for an improved mode of procedure; punishment of the insane; mitigated penalties; dispensable conditions; Does insanity diminish the expectation of life? 823—829.
- Insanity, editorial observations on the plea of, 152; editorial observations on medical evidence in cases of, 241.
- Insurance certificates and the medical profession, editorial observations on the legal decision respecting the payment of, 632.
- Insurance offices, remunerating and non-remunerating, 730.
- Intramural interments, abolition of, 598.
- Irish lunatic asylums, parliamentary return respecting, 87.
- Jacksonian prize, subject of the, for the ensuing year, 216.
- Jamieson's, Dr. lectures on the medical jurisprudence of insanity (see "insanity. Dr. Jamieson's lectures on the medical jurisprudence of").
- Jennette, M. on inflammation and abscess of the uterine appendages, 271, 472.
- Jough, Dr. on the three kinds of cod-liver oil, reviewed, 159.
- Johnson's, Mr. Henry Charles, introductory remarks to the opening of the session 1850-51, at St. George's Hospital, 605.
- Kenney's, Dr. case of wound of the brain, recovered from, 132.
- Kesteven's, Mr. case of probably intra-uterine acute inflammation of serous membranes, 141; case of fatal congestion of the brain, 238; on the unjust attack on the medical profession in the evidence on intramural interments, 345; case of presentation of the back at the full period of gestation, 404; case of puerperal uterine phlebitis, 926; case of portal phlebitis, and cases of jaundice, 1088.
- King's, Dr. remarks on epilepsy, reviewed, 460.
- King's College Medical Society, the president's address, 853.
- King's College Hospital:—Operation for femoral hernia, 81; for stricture, 81; Tuliacotian operation, 82; removal of a deformity caused by a burn, 211; removal of tumor of forehead, 211; of tumor of upper jaw, 212; lithotrity, 468; stricture, 465; excision of the knee-joint, 683.
- King's College Hospital, legacy to, 815.
- Kingdon's, Mr. J. A. case of sloughing of a malignant tumor which contained the femoral vessels, 576.
- Kirk, Mr. J. on irregular contraction of the uterus, 536.
- Kirkes, Dr. on the association of chorea with rheumatism and disease of the heart, 1004, 1049.
- Knee-joint, case of excision of the, 683.
- Knowles, Mr. on the climate of Madeira, reviewed, 807.
- Kramer's, Dr. case in which a slight injury to three fingers was followed by fatal consequences, 462.
- Landouzy, M. on nephritic amaurosis, 772.
- Lassaigne's, M. chemical tests of cerebral matter, 589.
- Latham, Dr. R. G. on the varieties of man, reviewed, 849.
- Lead paralysis, Dr. Colton's case of, 479.
- Lead, Mr. Herapath, on slow poisoning with, 518; Dr. Greaves on the action of the sulphite of, on dogs, 836.
- Lebert's, M. case in which a portion of mucous membrane was expelled from the uterus during menstruation, 210.
- Lecanu, M. on the preparation of pills of iodide of iron, 340.
- Lee, Mr. Edwin, on the brain, reviewed, 891; on the baths of Rhenish Germany, 892.
- Lee's, Dr. analysis of 108 cases of ovariectomy which have occurred in Great Britain, 893.
- Legrand, M. on a new mode of removing wens, 210.
- Life insurance, importance of, to medical practitioners, 556.
- Life, average duration of, in the New World, 777.
- Liebig and Kopp's annual report of the progress of chemistry, reviewed, 769.
- Liverpool Medical and Pathological Society, proceedings of the:—Dr. Nevins on tetanus in an infant, 981; Mr. Harris's case of hernia through the linea alba, 982; Dr. Nevins' case of superfetation, 985; perforation of a large artery in the stomach, 983; Mr. Banner's case of scirrhus mamma, 983; Mr. Hakes' case of cancerous testicle, 983; Mr. John Taylor on the efficacy of the tampon in uterine hemorrhage, 983.
- Liverpool Medical and Chirurgical Society, proceedings of the:—Mr. Paterson's case of abscess of the liver, 71.
- Lobelia inflata, experiments on the poisonous properties of, 285.
- Lobelia quackery in Cumberland, editorial observations on the, and on the inefficiency of the law in repressing quackery, 372.
- Low's, Mr. inquiry into the nature of the simple bodies of chemistry, reviewed, 935.
- Loudon Hospital:—case of dislocation of the

- thigh into the foramen ovale reduced after four weeks, 119; stricture impassable to instruments, 816; ununited fracture of the femur, 837; hernia, 860; operations for malignant growths, 989.
- London Hospital, appointment of the Duke of Cambridge life governor of the, 262.
- London medical schools, French summary of the, 774.
- Lonsdale, Mr. on some of the more practical points connected with the treatment of deformities, 339, 617.
- Lunacy, statistics of, 953; law of, 997.
- Lunatic asylums, reviews of reports of, 417, 422.
- Lunatic asylums, public and private, the census of 1851 in relation to, 1081.
- Lunatic ball at St. Luke's Hospital, 730.
- Lutrand, M. on the preparation of collodion, 590.
- Lymphatics, Dr. Fetzner's case of disease of the, 997.
- McCreedy's, Dr. case of poisoning by corrosive sublimate, 461.
- Macpherson, Dr. on Bengal dysentery, reviewed, 1026.
- MacLise's surgical anatomy, parts 6 and 7, reviewed, 769.
- Maitland, Dr. on mesmerism, reviewed, 845.
- Maisonneuve's, M. case of reduction of long-standing dislocation, 118.
- Manchester Medico-ethical Association and the poor-law board, 437.
- Manslaughter, editorial observations on the toleration of, by unlicensed practitioners, 455; report of a trial on a charge of, for poisoning by lobelia inflata, 384.
- Martinet, M. on the application of electricity in diagnosis, 304.
- Marson Dr. case of disease of the spinal cord in which the symptoms supervened upon a recent cold, 103.
- Matico, employment of, to arrest hæmorrhage, 337.
- Matter, Mr. Low on the divisibility of, 972.
- Mattenczi, Professor, abstract of the fifth series of his electro-physiological researches, 175.
- Mayo, Dr. on the case of Mr. Dyce Sombre, 123; on the use and abuse of alcoholic liquors, 783.
- Measles, Mr. Noble on the occurrence of, sporadically, in new-born children, 354.
- Medical appointments, 1085.
- Medical Society of London, proceedings of the:—Mr. Coulson on extra-capsular fracture of the thigh-bone, 726; Dr. Bennett on angina membranacea, 727; Dr. Semple on valvular disease of the heart, 770; Mr. Walton's case of enormous fatty tumor, 812; Mr. Pilcher on certain affections of the nervous system simulating chorea, 813; Dr. Webster on the health of London, 850; Dr. Hare's remarks on the same, 897; Mr. Brown on the treatment of ovarian dropsy by the production of an artificial oviduct, 939; Mr. Canton's case of aneurism of the aorta, 941; Mr. Hunt on mercury in syphilitic eruptions, 941; Dr. Snow on an inhaling apparatus, 1026; Dr. Cormack's case of cauliflower excrescence of the os uteri, 1026; Dr. Snow's case of enlarged heart, 1028; Mr. Henry Smith's case of false passage in the urethra, 1028; Mr. Cox's case of laryngismus stridulus, 1028; Dr. Lankester's case of aneurism of the arch of the aorta, 1079; Mr. Gay's case of non-united fracture, 1079; Mr. Walton's case of excision of the head of the femur, 1079; Mr. H. Smith's case of erysipelas in an infant, 1104; Mr. Child's case of anencephalous fœtus, 1104.
- Medical Society of London, appointment of professors at the, 687.
- Medical trials and inquests:—Death from chloroform in surgical operations, 39; trial for murder by poisoning with corrosive sublimate, 253; on a charge of manslaughter for poisoning by lobelia inflata, 384; report of the trial of Dr. Webster for the murder of Dr. Parkman, 431, 467, 506; action for recovery of charges in attending as a physician, 687; trial of John Stauff for the murder of the Countess of Goerlitz, 899, 944.
- Medical evidence, a specimen of, 262; incompetency of, in certain cases, 413.
- Medical teaching in the United States, 1042.
- Medical relief in Ireland, 216.
- Medical reform, balloting questions of the National Institute, 40; report of the south-eastern branch of the Provincial Association, 127.
- Medical portraits, recent, critical notice of, 546.
- Medical Protection Office, the affairs of the, 738.
- Medical students in Paris and London, increase of, 997.
- Medical session for 1850-51, remarks on the opening of the, 542.
- Medical education in Spain, 568.
- Medical education in the United States in the European medical schools, editorial observations on, 671.
